There has recently been placed on the market a swing cut-off saw driven by an electric motor directly on the saw arbor. The advantages of such a design are obvious, because there are no belts, no pulleys and no countershaft. The arbor revolves on ball bearings and the guard is self contained. The type of motor used as standard on this design of swing saw is furnished only in two or three phase, 60 cycle, 220 or 440 volts, A.C. to 3 horse power at 300 r.p.m. The motor is of the shaftless type assembled on the saw arbor. A 16 in. diameter saw with a guard and handle integral with the frame is furnished. There is no power lost in transmission through the pulley belt and countershaft, as these parts are eliminated. Thus, as the moving parts are reduced in number, efficiency is obtained, there is less to get out of order, and the machine requires a minimum of attention. Another feature is that the operator is not exposed to the danger of a broken belt, which might cause direct injury or throw odd blocks around. The control of the motor is through the medium of a push button located directly above the motor in the frame. The machine is manufactured by the Oliver Machinery Co. of Grand Rapids, Mich. and is known as their saw No. 36. This same saw can be furnished motor and belt driven in the old design.

UPRIGHT DRILLING MACHINE

A 32 inch electric drilling machine, driven by a motor of the vertical shaft design, is a recently developed tool. The motor is mounted on the top of the column. The armature shaft is hollow and the spindle of the machine extends through the hollow shaft. The hollow motor shaft does not drive the drilling spindle directly but through a train of plain and sliding gears which gives nine spindle speeds. The feeding mechanism provides for six feeds ranging from six one-thousandths to thirty-five one-thousandths per spindle revolution. The table is equipped with the usual facilities and adjustments, and can be supplied in either round or rectangular types. The standard motor supplied is of the reversing type, which feature is useful in tapping operations. Either alternating or direct current motors are provided, 3 h.p. for ordinary work, and for rapid work a 5 h.p. motor running 1,800 r.p.m. is recommended. Some of the principal specifications are as follows: Maximum distance from base to spindle nose, 56 inches. Minimum distance from base to spindle nose, 15½ inches. Vertical traverse of table, 16 inches. Maximum distance from table to spindle nose, 37 inches. The machine is capable of driving a 3-inch high-speed drill through steel, and weighs about 3700 pounds. Placed on the market by Prentice Conradson of Green Bay, Wis.

NEW CHAIN PIPE WRENCH

An improved design of drop forged, double jaw, chain type of pipe wrench has recently been placed on the market, in seven sizes with capacity suitable for use on pipes and fittings from ⅛ inch to 16 inches diameter. Two types of chains can be provided, either the cable or flat link chain. Several weak points, developed in extensive use and exhaustive tests of previous designs were taken into consideration, and it is claimed that the undesirable features have been eliminated in the new design. The tendency of the jaws to work loose on the bar with the resultant spreading of the rear end of the jaw and the wedged or jammed chain, has been done away with. The jaw-sockets are provided with considerably increased bearing surface. Two hardened chrome nickel steel bolts hold the jaws rigidly in place under conditions of severe use.

The rear bolt is located directly under the chain socket where the spreading is greatest. Chain guides are provided on the jaws to protect the finished end of the bar from wear and tear of the chain, and also to make the adjustments of the chain easy and convenient. In addition, the guides prevent the chain from jamming in the end slot of the bar. The handles are forged from high carbon steel and have the stiffness and spring needed to stand up under hard service. The drop forged jaws are made from special steel, treated, hardened, and tested for toughness and lasting qualities. The chains are of the best quality and tested to insure proper service. This wrench is manufactured by the Armstrong Bros. Tool Co., Chicago, Ill.

TOOL ROOM LATHE

A 14-inch tool room lathe which is driven either by a cone pulley or an all-geared head has recently been developed. In the all-geared head all gears run submerged in oil. The spindle speeds are arranged in geometrical progression from 13 to 326 revolutions per minute. The speed changes can be accomplished while the machine is in motion. The spindle is equipped with a friction clutch which stops the spindle immediately when the clutch is disengaged. The spindle bearings are oiled from a reservoir. The quick change gear box is equipped with a tumbler and eight gears, the setting and operating of which is by means of a lever. This gear cone permits of 48 different threads and feeds. The feed box is easily disengaged. Extra gears are provided which when used, permit of an extremely wide range of feeds and threads.

The apron is of a box construction and all gears are enclosed by a plate on the rear side. Provision is made for disengaging the rack pinion from the rack when desired. A sensitive clutch for throwing in both the longitudinal feed and the cross feed is located in the apron. A separate feed rod and reversing rod are provided. The lever for reversing the feeds is located on the apron. Collars that can be set in any desired position on the feed rod provide automatic stops for the carriage. The lead screw is directly connected to the cone of gears in the feed box. Micrometer stops are provided on the cross slide. The tail stock is clamped by a device at the back but which is conveniently operated from the front. Boring and counter-boring operations are facilitated by the provision of a collar on the tail stock which is graduated to 0.001 of an inch. A relieving and a taper attachment are both provided. The latter is so arranged that no strain is placed on the attachment, which is graduated both in degrees and in inches per foot. When it is desired to drive the lathe by a motor, it is supported on a bracket attached to the back of the left hand leg and thus the necessity of an idler pulley is eliminated. Manufactured by the Rockford Tool Co., of Rockford, Ill.

A large amount of construction work is projected, much of which will be proceeded with during the present year. The greater part of the new tonnage now being placed is for structural steel. The various industries are buying moderate tonnages as necessity dictates.

Prices Are Coming Down

THE CANADIAN markets show over twenty price changes this week. Scrap metals are hit worst of all. It is significant that every change is downward, and not upward, as dealers often hint is likely to happen, but for which Canadian Machinery has had no hope whatever. There can be no real revival of business until costs and production get to the same low prices as our basic industry, agriculture.

This is worse than a buyers' market, because at present prices consumers positively refuse to buy excepting for a few necessary requirements. Dealers are beginning to realize the foolishness of resisting the inevitable, and are again making an effort for buyers, by a further reducing of prices.

The losses incurred by dealers in iron, steel and scrap, not to consider other lines, have been very heavy, amounting to hundreds of thousands of dollars. In the meantime, the consumer is having his revenge for the days when he had to plead, figuratively speaking, on his knees for any desired material.

Let Us Save All We Can

THE AMOUNT of material wasted annually in machinery plants is enormous. A casual walk through the warehouses and yards of any large scrap metal establishment would convince even the most skeptical of the value of scrap reclamation.

We recently visited the premises of one such firm and while expecting to find a considerable amount of scrap, the actual conditions were even worse than we had anticipated. One pile alone contained over 60,000 pieces of scrap which were only five thousandths under size. What the pieces were originally intended for is immaterial. The point is that carelessness was costing this plant an immense amount of money. Unfortunately these particular articles were so constructed that reclamation was impossible and the loss was thus a double one.

Many pieces, however, reach the scrap yard which could easily be reclaimed. In one scrap warehouse we visited, special piles, consisting of material purchased as scrap, were being saved to sell at a very large profit.

Railway shops are now firm believers in scrap reclamation. The C. P. R. have a very complete reclaiming department at Montreal which is more than paying for itself. In the summer, when haulage is most favorable, the scrap is sent to the reclaim section to be carefully sorted over. The various parts are reclaimed, arranged and reassembled into articles which can once more be used. Those interested in this matter can refer to our September 2, 1920, issue, which gives a detailed account of the department we speak of.

Every plant cannot go into the reclaiming business on as large a scale as the C. P. R., but any firm can adopt a method of recording the percentage of scrap passing through the factory, and arrange to have scrap material sorted over. Those who have never done this will be agreeably surprised at the results. Instead of a miscellaneous pile of material, commonly termed junk, being placed on the scrap dealer's wagon, any plant can see to it that when a dealer calls for junk, that is what he gets, and not valuable material. Some metals command a better price than others, and a man's time is well spent sorting the material over.

Employ an intelligent man for the purpose, otherwise you may defeat your object. A good man may cost more per hour, but he will in turn save more. A conscientious man is necessary, one who feels an interest in his work, and enters into the spirit of it. A bonus on the value of material salvaged is one good method of securing efficiency, this value to be determined by the foreman.

Coal Prices Must Come Down

ON PAGE 50 appears an article on "How Dear Coal Costs Railroad Jobs." It shows that so called loyalty to one's business or union may often be bad for one's own personal interests. An alliance between the United Mine Workers and the railroad brotherhoods would be an unwise step for both parties. To pool the wage question would only make matters worse, and the railroad unions would be putting their finger in their own eye.

Even at the present time we find railways all over Canada and the States laying off employees owing to lack of traffic. To fight the much needed wage reductions would only aggravate existing unsatisfactory conditions and force the railways to further curtail their staffs.

Loyalty is all right in its place if the cause is just, but to be loyal to a union, society, firm or other concern merely because you have a sentimental interest in the matter is the height of foolishness. The biggest men in the public eye have at times stepped aside when they felt their party, or firm, was not serving the country as it should. This is true loyalty.

Concerns of a speculative character would do almost anything to have the names of such men on their lists of directors for stock selling purposes, but they know how futile any attempt to secure their consent would be. Loyalty, tempered with common sense, is an ideal combination.

A census taken of manufacturers in the United States shows that in 1919 there were 289,768 manufacturing establishments employing an average number of 9,103,200 employees. The factory value of the products turned out represented the total of $62,910,000,000 or $25,537,000,000 more than the cost of materials used.

Recent Developments in Mechanical World

Scrap Metals Show Drop in Price

Non-Ferrous Metals Taper Off In Montreal—Steel Market Weak In Toronto and Montreal—Machine Tools Considerably Brighter—Small Tools and Supplies Continue Active

BETTER FEELING IN ALL MARKETS

TWENTY-three reductions in price have taken place on the Canadian market this week. Scrap metals have been hard hit, boiler plate, heavy melting steel, scrap rails, malleable scrap, cast iron No. 1, wrought pipe car wheels, cast borings, and stove plate all being affected. It is an effort on the part of dealers who are carrying big stocks to stimulate business on rumors of the withdrawal for an indefinite period of one of the most important buyers.

A larger discount on several milled products is now in effect. Iron pipe fittings are also cheaper.

Pig iron is not much in demand, but sheets are fairly steady. The steel market locally is none too brisk, and this same condition holds good for Montreal. Competition continues keen, price shading being the rule. No reasonable bid is turned down.

Machine tools locally continue to improve. They are even better than noted in last week's report. Dealers are discovering prospects in unsuspected territories, and are following up such business closely with the result that some much needed orders are being secured. Montreal reports machine tools to be very quiet.

A decided improvement has taken place in the demand for small tools and supplies. Garage dealers, and the automotive trade generally are both responsible for the increased sales. Compared with the peak days, sales are far from normal being around 45 per cent., but the volume of existing business is encouraging under the present circumstances.

A spirit of confidence exists on all markets which is worth noting. This feeling is getting stronger every week, and dealers are sure the turn has been reached, and that once spring opens up, so will business.

Toronto Markets

SO FAR this week, twenty-three price reductions have taken place on Canadian markets, the majority being in scrap metals.

Scrap boiler plate dropped $3, being now quoted at $9; heavy melting steel is down $2, to $12; scrap rails are selling at $12; malleable scrap at the same figure, and No. 1 machine cast iron at $19.

Wrought pipe is quoted at $6, in place of $8, and car wheels are selling at $18. Stove plate is quoted at $16, and cast borings at $6. Compared with 1914 prices, these figures range from 10 to 40 per cent. above the price existing at that time. The demand in these lines has been so slight, that dealers decided to make the move in an effort to stimulate business. Manufacturers are purchasing only for immediate requirements, this preventing dealers unloading their large stocks of scrap. The great majority of this material was purchased at high prices so that dealers will simply have to wipe off their losses. Following are the new prices in table form.

Boiler plate	9 00
Heavy melting steel	12 00
Axles (wrought iron)	20 00
Rails (scrap)	12 00
Malleable scrap	12 00
No. 1 Machine cast iron	19 00
Pipe, wrought	6 00
Car wheel	18 00
Steel axles	18 00
Mach. shop turnings	6 00
Stove plate	16 00
Cast boring	6 00

Pig Iron.—This market is still quoted at $27.15, but even at this figure the demand is very light. Until foundries open up, no change is expected.

Non-ferrous Metals. — Local prices remain firm, but demand is very light. Montreal made a few changes to this section of the market, lake copper, electric copper, and spelter being the metals changed. However, the reduction made in Montreal field merely brings them more in line with local prices.

Machine Tools.—Increased business is reported in this section. Orders have not been for large quantities, but several dealers are quite sure the worst is over. The majority of orders secured have been obtained by very hard work, and close follow up. In fact the most out of the way fields are being combed for business, with surprisingly satisfactory results. One dealer aptly expressed the situation by remarking that in the present market you can never tell where your next order is coming from.

Milled Products.—Several new discounts have come into force on milled products. Below are given the different changes.

Set screws	Less 55%
Square and hexagon head cap screws	Less 50%
Round head cap screws	Plus 10%
Fillister head cap screws	Less 10%
Flat head cap screws	Net list
Button head cap screws	Plus 10%
Studs	Less 35%
Semi-finished nuts up to and including 1-in.	Less 60%
Semi-finished nuts 1⅛ to 2 in.	Less 25%
Semi-finished nuts 1¾ to 2 in.	Less 25%
Coupling bolts	Less 10%
Taper pins	Less 60%
Planer bolts without fillet	Plus 25%
Planer bolts with fillet	Plus 35%
Patch bolts	Plus 50%
Hollow set screws	Plus 10%
Thumb screws	Less 60%
Thumb nuts	Less 85%

Small Tools and Supplies—Business in the small tool market continues to improve. The volume of orders received last month was much better than even the dealers themselves expected, and the present month is also showing up to good advantage. Prices remain steady, no change is expected, as several reductions have already taken place.

Steel Market.—A little better feeling exists in the demand for steel. Nothing is featured, any call being general in character. Prices remain unchanged, but shading exists in some lines. February is never a bright month for the steel trade, but it is a little better than was expected under present conditions.

Miscellaneous.—Pipe fittings show several changes this week. Cast iron fittings record a larger discount, also malleable bushings, unions, and plugs. Following are the new discounts.

	Black	Galv.
Class A	54	67
Class B	20	28
Class C	13	20

Cast iron fittings, 30%; malleable bushings, 32%; cast bushings, 32%; unions, 47%; plugs, 30% off list.

Oils and greases are not much in demand, manufacturers only purchasing for immediate requirements. This same condition holds true in other lines, but apart from the changes recorded in this letter, and on the quotation pages, other prices remain firm.

The proposed new machinery hall for the Toronto Exhibition may not be erected this year. In fact it is hardly likely that it will be. Location and plans seens to be the chief difficulties at present, and in about a week this matter will be discussed and probably settled. Plans for the new structure

will be gone into, and it is very likely that somewhere near the Strachan Ave. entrance will be chosen as the new location.

Montreal Markets

THERE has been no marked improvement in the Montreal field during the week. Steel is listless, no drop in steel prices has occurred, but owing to scarcity of orders, shading continues. Jobbers are experiencing keen competition with the sales representatives of the mills, and do not appreciate the situation.

Pig Iron.—The price reduction which occurred a few weeks ago on this metal has not helped the volume of business. The effect of the reduction may not be felt for some time yet, and generally speaking, things are very quiet.

Non-Ferrous Metals.—This section continues weak, and several prices have been shaded a little. Lake copper has dropped from $17.50 to $17.25; electric copper is down to $17.00; copper castings to $16.75, and spelter $7. Apart from these figures the other metals remain the same.

The large users of metals are operating at only a small fraction of their capacity, and little raw material is being purchased. There is no prospect any change. Following are present quotations:

Lake copper	17 25
Electric copper	17 00
Castings, copper	17 25
Tin	35 50
Spelter	7 00
Lead	6 50
Antimony	6 50
Aluminum	24 50

Scrap Metals. With pig iron, steel, and non-ferrous metals all quiet, it is only to be expected that the trading in scrap would be light. Little or no business is offering and prices are weak.

Machine Tools.—Conditions are very quiet on this market. Machines are being purchased more intelligently than heretofore, but orders are not frequent. Dealers are scouring the territory for prospects, in the hopes of stimulating this branch of the market.

Small Tools and Supplies.—Dealers are securing good business in the above mentioned lines. Competition is keen, but clean cut. Garages are proving a good source of business, and have helped to increase the sales. As manufacturing plants are not very active at present, the volume of business is bound to increase when things start to open up. This means that for the next few months we can look for a gradual, but steady improvement in demand.

Miscellaneous.—Plates are very quiet, also merchant bars while sheets are fairly active. The prospects for a busy building season look rosy, in fact construction is going on in many quarters at the present time. Apartment building is being pushed, and the Foundation Co., are actively engaged on the preliminary work on the new Provincial Government Building.

The G. T. R. have announced that they will increase their elevator capacity at the Port of Montreal by building an addition to the Windmill Point Elevator, capable of accommodating an additional million bushels of grain. They also intend to install a car dumping machine, and a second carrier for delivering grain to ocean vessels. C. J. Smith, manager of the Montreal Warehousing Co., under whose jurisdiction the G. T. R. elevators come, has already called for tenders. The present intention is to have the car dumping plant, and the additional loading facilities completed and in operation by the time navigation opens. The addition to the elevator should be ready for grain about the first of June, or in any event in plenty of time to take care of any demands made upon it by the 1922 crops. These various projects all have their bearing on the steel trade and are supplying a small amount of business all the time.

Pittsburg Markets

PITTSBURGH:—(Special to Canadian Machinery.) Steel ingot production in January shows that the steel demand was heavier than expected. As noted in previous reports, while there was sharp competition for months, it became more widespread and vigorous right after the first of the year. Apparently the condition was, that each mill preferred not to let its competitors know how much business it was doing, lest still sharper competition would be provoked, and assumed that its competitors were not doing well or they would not make such close prices on small orders.

It was an increase in demand, rather than an absence of demand, that increased the price competition. That is according to precedent in the steel market. In a dull market, when there is no business, the mills "sit tight." When there is business, and they have not enough, they go for it. The character of the steel market for some time to come is plainly shown. There will be a moderately fair demand, decidedly better than the demand in 1921, and the orders placed will be small individually, but numerous, all for prompt shipment. It will be hand to mouth buying, the kind mills frequently refer to of being not much account, but what they mean is that it does not give them a chance to schedule their rollings efficiently or advance their prices. Given a certain consumption, the tonnage of steel is the same whether the purchases are for prompt or extended delivery.

Steel Production.—Reverting to the report on January steel ingot production, the American Iron and Steel Institute reports each month the production of 30 companies, which make something like 85 per cent. of all the steel ingots, and a close estimate can be made of the production of the industry. In approximate figures, the industry produced steel ingots at the rate of 22,750,000 gross tons a year in January, 19,750,000 tons in December, 23,000,000 tons in October and November, and 11,000,000 tons last July, viz, the low point, when there was extensive liquidation of stocks of steel in the hands of jobbers and manufacturing consumers, and liquidation of stocks of manufacturers of steel.

The increase in the rate from 19,750,000 tons a year in December, to 22,750,000 tons a year in January does not tell the story of the rapid increase in demand. It will be understood that in a market like this, when purchases are deferred to the last moment and mills fill orders very promptly, the rate of steel ingot production reflects accurately and quickly the volume of buying of rolled steel. During December, with an average for the month as indicated, the rate was going down, and was below 18,000,000 tons at the close of the month. Starting from this low rate and making an average as indicated for January, the rate at the close must have been well above 23,000,000 tons. That is, the rate increased in one month by fully one-third.

The low demand for a while was due chiefly to its being winter, for when buyers are buying only as they are forced to do so, holidays and inventory would not stop them. The spring demand is beginning to develop, and there is ever reason to believe that its top point will be well above what has been shown. Last autumn's demand, which came after liquidation of stocks was practically completed, brought a rate of ingot production for two months of 23,000,000 tons. This spring will no doubt witness a rate of between 25,000,000 and 30,000,000 tons.

As underlying conditions gradually improve, each wave of demand should rise higher, and next autumn should see something heavier still. In the past, seasons have not made much impression on steel buying and steel production, because the steel capacity was smaller and the mills had to run more steadily, while buyers anticipated their requirements, out of season, to make sure of deliveries. Now they need have no concern on that head, and so steel production will rise and fall with the season.

Prices Irregular.—The steel market as a whole cannot be quoted. There are certain regular, nominal, or asking prices, which have not changed for nearly two months, but week by week departures from these prices have become more frequent, in two ways, by concessions being made on smaller tonnages than formerly, and by mills in various sections departing from "Pittsburgh plus" or the system of having a standard Pittsburgh price and quoting delivered prices at that figure plus the rail freight from Pittsburgh to point of delivery.

The regular prices, for leading commodities, are: Bars, shapes and plates, 1.50c.; standard steel pipe, 71 per cent. basing discount; plain wire, 2.25c.; wire nails, $2.50; blue annealed sheets, 2.25c.; black sheets, 3.00c.; galvanized sheets,

(Continued on Page 43)

4.00c.; tin plate, $4.75. The sheet prices are quite well held, while all others are shaded more or less. On moderate sized lots 1.40c. can be done on bars, shapes and plates, and $2.40 on nails, for instance. South of the Ohio river, on account of the Ironton district mills, the Pittsburgh basis is commonly ignored. In bars, shapes and plates, Chicago has had a market of its own for a long time, and Buffalo for a shorter time, while the east generally now has its own prices when anything like large lots are involved.

Tonnage.—The Steel Corporation's unfilled tonnage at the end of January is reported at 4,241,678 tons, showing a decrease of 26,736 tons during January, against an increase of 17,872 tons during December. The important point is how much steel the corporation is permitted by customers to ship, it being of no consequence whether the shipment is against a contract placed in 1920, or a new order placed the day before. The corporation's shipments in January were about 650,000 tons, or approximately the same as in December, representing 47 or 48 per cent. of capacity.

Pig Iron can hardly be said to be quotably changed but the market appears to be somewhat easier. Regular quotations remain at $19.50 for Bessemer, $18 for basic and $19 for foundry, f.o.b. valley furnaces, with $1.96 freight to Pittsburgh. A lake front furnace has sold 500 tons of foundry iron for delivery at Pittsburgh at 50 cents less than the cost of valley iron would have been at $19, furnace. Lake front furnace competition is generally more or less a factor in Pittsburgh when demand is light.

Connellsville coke has been stiffening, doubtless on account of the general belief that there will be a suspension at the union bituminuous coal mines, April 1, which would throw still more coal demand upon the Connellsville region. It is difficult to pick up spot foundry coke now at $3.75, at least for a fair grade, while one favorite brand, long held at $4.25, is temporarily withdrawn from the spot market on account of the requirements of holders of regular contracts for the brand.

SECURE CANADIAN PLATE BUSINESS

A NOTICEABLE improvement has taken place in the British tinplate trade, according to H. M. Trade. Commissioner, Toronto, and it is estimated that the present output is about 75 per cent. of the normal pre-war capacity. The number of mills now in operation is said to be sufficient to absorb all the available labor and quite a number of works have enough orders to last them for a few months. Buyers are showing much greater confidence in the market and a feature of the last few weeks has been the number of option contracts placed by merchant firms for forward deliveries.

The Welsh tinplate makers were recently able to secure, in the face of American competition, an order for 150,000 boxes of tinplates for the British Columbia packing industry. Their success was in no small measure due to the low freight rates now ruling direct from Swansea to Vancouver. The British Columbia market has practically been a preserve of the U.S. tinplate manufacturers for the last ten years.

Stainless Iron

Referring to developments regarding stainless iron, it was pointed out that experiments have for some time past been conducted with the object of producing material possessing the rust and stain resisting properties of stainless steel, but so ductile that it can be employed for purposes for which stainless steel, by reason of its hardness is unsuitable, especially for cold working in articles of intricate shapes, and for articles where. although they may len themselves to manufacture in stainless steel, it is impracticable to apply the heat treatment which rustless steel requires.

GREAT BRITAIN LANDS MANY CONTRACTS

"DEVELOPMENT WORKS have been held up all over the world since 1914, and although the economic situation is still retarding normal progress, demand is accumulating and must be satisfied sooner or later," says Albert S. Spencer, member of the Steel Structural Committee of the British Engineers' Association.

"In Great Britain we have structural materials of all kinds ready to hand," continues Mr. Spencer, "but steel has forced its way to the front as the most reliable and economical of them all for the main structural parts of industrial and other important buildings. This is true of most countries abroad, as well as at home, since steelwork, apart from its low cost, can be imported all ready for assembling by local labour. In pre-war days the structural steelwork for a multiple-storeyed building was obtainable for about 20 per cent. of the total cost of the building. To-day, owing to the relatively low cost of structural steel as compared with other building materials, the proportion is nearer 10 per cent. These figures are eloquent of the economy inherent in structural steel, whose other advantages are:

"I. Area for area steel will support 35 times as much as stone and 140 times as much as brick; therefore a steel-framed building is considerably lighter than one of brick or stone. It is the only possible material where a multiple-storey building is to be erected on a limited site.

"2. The steel-framed building, although having less mass than one of brick or stone, has greater stability if properly designed, and is better able to withstand such natural forces as wind pressure and the strains set up by earthquakes and similar disturbances.

"3. Structural steel work can cover large spans. Compare almost any steel-framed building with one of reinforced concrete, brick, or stone. In many cases the lower storeys of the latter have the appearance of a series of alleys rather than the spacious rooms obtained by the use of steel. This advantage is very great when rent value is being determined.

"4. Other advantages of steel-framed buildings are: Better facilities for utilising natural light; ease of reconstruction when internal rearrangement is necessary; and speed of erection, enabling the variaus trades to operate on any part of the structure, even to the point of working from the roof downwards."

Mr. Spencer goes on to point out that Great Britain has landed many important contracts abroad recently, and mentions the following:—A fifteen-span bridge over the Ganges, involving 30,000 tons of steel; the steel structural work of the market at Johannesburg; the railway station at Retiro, Buenos Aires, involving 2,150 tons of steel; the power station at Melbourne, involving 5,000 tons; a railway viaduct for Bolivia, 240 metres long and 93 metres in height; the wharf sheds and jetties at Rangoon (this was a contract worth about £250,000); and the structural steel and bunkers for a generating station in Alaska.

METHODS OF REDUCING MANUFACTURING COSTS

(Continued from page 31)

items that he was able to undersell all his competitors and still increase his profits.

Elimination of Waste

"In the elimination of waste each plant has its own problems. Waste may result from low production, an interruption of production or idle machines. Improper buying, idleness in certain sections of the plant, improper sales policies, all have their share in augmenting waste. Labor turnover, the hiring of unskilled workmen, the prevalence of disease among the workers, are all factors. Waste may be lessened by the use of labor-saving machinery, greater thrift in power, the use of proper lubricants, covering the pipes with insulated material to conserve heat in its transmission, better bearings, the adjustment of leaky valves, and keeping the machines free from dust and dirt so that they will operate smoothly.

"The use of conveyors or chutes to carry articles from floor to floor cuts costs on both labor and power. One organization which finds it necessary to use elevators, times its one-man trucks so that they load an elevator to capacity without delay.

"How do you keep your department always moving so rapidly and at such a high grade of efficiency? I asked one man.

"'My department is always overpaid and understaffed!' he replied sententiously.

"Modern methods of cost accounting have enabled us to put our finger on many of our troubles but they have not solved them all."

SELECTED MARKET QUOTATIONS

Being a record of prices current on raw and finished material entering into the manufacture of mechanical and general engineering products.

PIG IRON

Toronto price:—

Silicon, 2.25% to 2.75%	27 15

News From the Industrial Field

An order-in-council has been passed authorizing the expenditure of $35,000 on steel rails for the Government railway.

General contract for electrifying a saw-mill at the cost of $60,000 for Thurston, Flavelle, Limited, Port Moody, is awarded to a Vancouver firm.

Preparations are being made for an early break up of winter in the Northern Ontario mining districts, and provision will be made by the Northern Canada Power Company to have plenty of power available for active operations, which are expected to surpass those for some years back.

Ontario has an overwhelming lead in the production of rubber goods, employing 7,655 persons as against 826 in Quebec province. Quebec leads in the manufacture of rubber footwear with 4420 employees as against 2,410 in Ontario. In all there are 24 rubber manufacturing plants in Ontario and only eleven in Quebec.

At the February meeting of the Toronto Association of Purchasing Agents an interesting talk on "How to Buy Coal" was given by the guest of the evening, E. C. Hanson The subject was received with great interest, in view of the threatened coal strike on April 1st. The annual election of officers of the association will take place at the March meeting.

The waterworks commission of Brantford, Ontario, plans for an addition to their pumping station including installation of three gauge centrifugal pumps with electric motors. The cost will be about $250,000. The city council of Goderich, Ont., plans improvement to waterworks system including erection and equipment of a new pump house, cost to be about $40,000.

To complete the plans for the successful manufacture of Saskatchewan lignite on a commercial basis, Hon. Charles Dunning stated that it would require an additional $250,000 to carry out the work. About $800,000 has been expended to date. It is expected that the required money will be granted jointly by the Federal Government and that of the Provinces of Manitoba and Saskatchewan.

The volume of trade between Canada and the United States was reduced approximately 45 per cent. during 1920. The value shows a decline of over $200,000,000 on Canada's exports to the States and a drop of nearly $400,000,000 on imports, representing a reduction in each case of about 60 per cent. The difference in volume and value rate is accounted for by the average drop in price of merchandise, which has been around 27 per cent.

The appointment of Mayor Robert McKnight, C. E., to the position of engineer for the county of Grey has been announced.

Messrs. Phillip J. Turner and A. J. Hazelgrove, architects, have removed their offices from 241 to 284 Beaver Hall Hill, Montreal.

A Dominion charter is being secured by the Peninsular Flour Mills of Dunnville, Ont., which has its head office in that town. A flour mill and elevator is to be erected.

As a sequel to the concentration of General Motors Corporation on export business at the Oshawa plant, the Oakland Motor Car Co., of Canada is being incorporated under a Dominion charter. A considerable proportion of the production of the newly organized company will be for export purposes only.

The feature of the February meeting of the Quebec branch of the Engineering Institute of Canada was an informal talk on the value of forest survey work and photography in connection with pulp and paper companies' timber limits. The chief speaker was R. H. Nisbet, forest engineer in charge of the aviation service of the firm of Price Bros. Mr. Nisbet stated that all aviation work was done in conjunction with the ground surveyers, and that in taking photos for map making purposes, as many as 300 an hour could be taken. The speaker intimated that while aviation would prove of great benefit to surveying, it would never eliminate the ground engineer.

Mr. E. N. Williams, Toronto, Ont., a few days ago, showed us a new invention which he calls a "Non-Slip Cable Socket." This socket goes inside the regular cable clevis, holding it securely, and lengthening the life of the cable. Instead of the usual babbitting process, the socket consists of two or more parts, these interlocking over the strands of the cable without injury in any way.

Mr. Williams showed us a letter signed by the master mechanic of the Hydro Electric Commission, proving that his idea was used for over two months on No. 2 shovel, which had a capacity of 12 cub. yds. During the time it was in use 94,412 cub. yds. of rock were lifted from cut, the natural strain on cable being approximately 87 tons. According to P. R. Reid, the master mechanic, the socket held the cable firmly and without trouble.

It is Mr. Williams' intention to start manufacturing this product in Toronto, and he has patented his device in Canada, at the same time having made his application to the U. S. Anyone interested can write him at 84 Massey St., Toronto.

The International Transit Co., Sault Ste. Marie, Ont., is contemplating ordering five one-man safety cars.

The Canadian Finance and Trading Corporation, 211 McGill St., Montreal, plans to build a two storey ice arena on Atwater Avenue, the cost to be about $400,000.

A. St. C. Ryley has been appointed general manager of the Montreal territory of the Trussed Concrete Steel Co. of Canada, Walkerville, Ont., succeeding G. B. Reynolds.

The London Street Railway management states that it is using every available car during the rush hours and that the service cannot be improved without the purchase of additional cars.

An inspection tour of the western lines of the C. N. R. is now being made by the Hon. W. C. Kennedy, the newly appointed Minister of Railways, and a number of the executive officials of the road.

The Mueller Mfg. Co., Sarnia, expect to have extensions to their line of steam valves perfected about April 1st. This will enable them to place on the market a complete line in this department, representing a new development in their industry.

The H. M. Lane Co., Detroit, have completed extensions, involving an expenditure of about $100,000, to the foundry of Hiram Walker and Sons, Metal Products, Walkerville. The foundry is now equipped to handle motor car parts on a production basis.

The H. H. Robertson Co., Sarnia, are completing the erection of a phosphate house for the Scotch Fertilizer Co., Welland. The structure is entirely of Robertson protected metal in which layers of asphalt and asbestos are combined, assuring resistance against chemical action.

The appropriation for construction and betterment for this year has been under consideration by the management of the Canadian Pacific Railway at Montreal. The result has not been announced, but a press report states that the estimates presented call for an expenditure of about $25,000,000.

James Shand, for many years superintendent of the Dodge Manufacturing Company, of Toronto, died recently at his home in that city. Mr. Shand was born in the north of Scotland 62 years ago. He came to Canada as a young man, and all his life has been connected with machinery production. For a while he was connected with the A. R. Williams Machinery Co., but left that concern to take over the duties he held, until his death, with the Dodge Manufacturing Co.

Mr. John Campbell was recently appointed engineer of the Water Works Department, at Dresden, Ont.

Arthur H. Laurent, formerly assistant deputy minister of the Public Works Department has been appointed chief engineer, to succeed the late E. D. Lafleur.

Furniture of Canadian manufacture is not subject to a great deal of competition. The recent exhibition afforded a chance to size up the quality of the Canadian factories.

The Canadian shoe manufacturers have the domestic market without much opposition. It is estimated that imported footwear amounts to not much more than 5 per cent of the total.

The Preston Woodworking Machinery Co. of Preston, Ont., has recently issued a revised edition of their catalogue covering wood-working tools and equipment. The book is 9 x 12 and of the loose leaf style.

The construction program of the Transportation Commission for the City of Toronto, for the coming season will take care of an expenditure amounting to $12,000,000. Over 50 per cent. of this total will be used for the purchase of new track work.

The furniture industry is likely to buy more liberally in the coming months than at any time since the end of the boom period. The makers of furniture are producing on a more active basis at the present time than they have been doing for the past sixteen months at least.

Information has been received from Brantford that quite a few new companies have established plants in that city during the past year. Among these are the following: Canadian Automatic Conveyor Co., Lockwood Textile Co., Parisian Knitting Mills, Schuler Button Co., The Brant Foundries, Ltd., Ruddy Manufacturing Co., a 100,000 bushel grain elevator for the Dominion Flour Mills, and other smaller concerns.

Metal works, wrought iron stairway, elevator enclosure with general iron work required costing eight million dollars, for the Mount Royal Hotel Co., Montreal, will be supplied by the Western Supply Mfg. Co., Winnipeg, Man. Contract for ornamental iron is placed with the Canadian Allis-Chalmers, Limited, Montreal.

A Detroit manufacturing concern has made an exhaustive study of the reflecting values of different colored paints and their relation to the work. From a purely technical standpoint, their reflecting values relative to white paint are as follows:—White, 100%; Light Green, 53%; Light Yellow, 49%; Light Buff, 44%; Light Grey, 27%; Brown, 6% and Red, 5%. It would seem that these figures would indicate the superiority of white paint for industrial uses. Seeing that quite a number of foundries are being sprayed with this white industrial paint, why not decorate the interior of all metal-working shops with this paint?

The town council of Wiarton, Ont., plans the installation of an electric pump and engine for the waterworks plant to cost $10,000.

The knit goods trade is enjoying active business for spring delivery. Some of the woolen manufacturers are fairly busy on piece goods for the new season's trade.

The Toronto Transportation Commission's order, given the Canadian Car and Foundry, Montreal, for 140 motor cars and 16 trailer cars, has been completed and the cars delivered. Of the 50 motor cars ordered from Canadian Drill Co., Preston, Ont., 8 were delivered by January 14, and further deliveries are being made at the rate of four or five a week.

Inquiries made of Canadian Chamber of Commerce in London, Eng., and other sources, reveal slow but steady improvement in the Canadian export trade to Great Britain and the continent. The recent improvement in Sterling exchange in dollar values and the gradual exhaustion of surplus stocks have caused a turn for the better.

Opinion as to the outlook regarding building was the keynote of several speeches the other night. Speaking of the recent convention of building and construction men in Hamilton, Mr. Carswell said: "I feel sure that the depression in our line is over, and in that I express the convention of three hundred men who met at that convention." Touching on the money situation as relating to trade between one country and another the speaker remarked. "As soon as the exchange rights itself and money can come here without loss there will be an improvement."

Canadian Merchandise is occupying a more favorable position in the home market than it did four of five years ago. There is no question that the people of Canada are more appreciative of the merits of goods of domestic manufacture. That fact is demonstrated by the actual figures compiled by leading retail merchandisers of this country. The statement made recently by Sir John Eaton of the T. Eaton Co., that 80 per cent. of the goods sold by his organization were of Canadian produc[illegible] came as rather a surprise to industrial and wholesale men.

Louis de Ibarra, a business man of Mexico City, and at present visiting Ottawa, interviewing the Minister of Trade and Commerce regarding better trade relations between Canada and Mexico, emphasizes the fact that the Government needs trade representatives on the spot, while Canadian houses should send their own men with power to conclude agreements without delay. If they speak Spanish, so much the better. Improved transportation is also a necessity.

Mr. de Ibarra states that the country is on a gold standard, and excellent banking facilities include branches of the Bank of Montreal. Better shipping facilities on both the Atlantic and Pacific Coasts are sought.

The International Burr Co., of Watertown, N. Y., will be the seventh new industry to locate at Belleville, Ont., within a year. The product of the plant is largely used in pulp and paper mills.

Mexico, wants cars, steel equipment, agricultural implements, flour, timber, paper, breeding cattle, and meals. Mexico exports vegetables, fruits, oil, coffee, tropical woods, and great quantities of sisal, of which binder twine is made.

The U. S. Cast Iron Pipe and foundry Co. announces that it has purchased from a Canadian syndicate, headed by Gordon Perry, in the U.S., the exclusive right to use the De Lavaud patent in the manufacture of cast iron pipe by the centrifugal process in the U.S., its possessions and in Cuba.

Reports from Russia are to the effect that three hundred and ninety-four oil tanks have been received here from Canada and 304 are en route. The steamers Canadian Seymour and Canadian Roger brought tanks, as well as miscellaneous cargoes of shoes, foodstuffs and agricultural implements.

Mr. E. A. Lunderville, formerly purchasing agent and comptroller of the Canadian Ingersoll-Rand, Sherbrooke, Que., has been appointed as sales manager of the Bawden Machine Co. of Toronto. Mr. Lunderville resigned from the Rand Company in 1917 in order to enter business on his own account. He then entered the Colonial Machinery Co. in Cowansville, Que., and became president and manager of that firm, but recently sold his plant to local competitors and moved to Toronto.

The Ontario Department of Highways has arrived at the conclusion that the present is a good time to get the market for structural steel. Indications are that a considerable amount of British construction will be proceeded with this year, and placing of orders is expected within the next few weeks. The structural steel men believe that when spring opens up there will be a good demand for steel for constructional work. The ordinary seasonal quietude will prevail until about April, according to the present outlook.

The British-American Fuel & Metals Ltd., McKinnon Bldg., Toronto, are representing in Canada, sixteen mines of the Pittsburg and Younghiogheny districts, also the West Penn. By-Products Co. The object of this company is to give a direct service between the mines and the consumer. In their fuel departments they have a production of bituminous coals of nearly 10,000 tons per day. The directors include some well known steel manufacturers and coal producers on this continent. The general manager, Major S. Snell, A.M.E.I.C., late Royal Engineers, states that the company has successfully sold fuel to consumers in Canada upon a technical basis, and that they are in a unique position to supply consumers with a fuel most suitable for their requirements and thus secure for them, the greatest economy and efficiency.

During the year 9,297 permits were issued for 11,291 buildings, having a value of $23,878,240. Compared with 1921, the number of permits was greater but the value less, namely, 7,378 permits, 8,574 buildings, value $25,784,732. The increase in value over 1919 was about $4,000,000.

Architect Price of the City of Toronto, in his 1921 reports is quite hopeful for the future. He states that the requirements of commercial enterprises were giving an increasing impetus to the construction of office buildings, and industrial interests were urging more warehouse accommodation.

B. Schuyler Edsall, son of Samuel S. Edsall, of the Bowmanville Foundry Co., of Bowmanville, Ont., has been appointed to a responsible position with the Norwich Union Indemnity Company of New York. Mr. Edsall is a safety engineer and is now in charge of the engineering department of this company.

German competition has practically destroyed Canadian trade with Great Britain in such lines as enamelware, aluminum goods and toys, but representations are now being made to the Board of Trade with a view to obtaining tariff protection for such goods against the German products. Trade as a whole, however, is picking up.

New construction in Canada during January reached a total of $8,392,600. The value of building and engineering work reported amounted to a total of $22,391,600, representing 529 different projects. During 1922, it was pointed out, residential building will undoubtedly be active, at approximately the same level of cost. There will also be much better activity along the lines of railroad and public utility rehabilitation.

Speaking of the possibilities of the shipping industry in Canada, an optimistic note was sounded by Robert W. Reford, president of the Robert Reford Co., Canadian agents for the Cunard Line, in stating that "I believe that there will be great improvement next year. As far as Montreal is concerned, normal conditions practically returned there during the past season, when more grain was shipped through that port than in any previous year. It was a record year for grain carrying steamers."

The consummation of negotiations that have been going on for a number of years between Canada and Australia, for some form of reciprocity, may be announced at any time. This is the substance of a statement recently made by Sir Joseph Cook, former Prime Minister and now High Commissioner in London for Australia. He remarked that, "the time is now ripe for a real effort to be made to adjust the fiscal differences between Canada and Australia." He stated further, that at present Canada sells to Australia nine times the value of goods purchased from Australia and that it would probably be only a short time when trading between the two countries would be on a more equal basis.

The annual report of C. W. Kirkpatrick, Commissioner of Industries for Hamilton, Ont., states that twenty-four manufacturing plants located in Hamilton during the past year. Four other companies established headquarters there but so far have not commenced manufacturing.

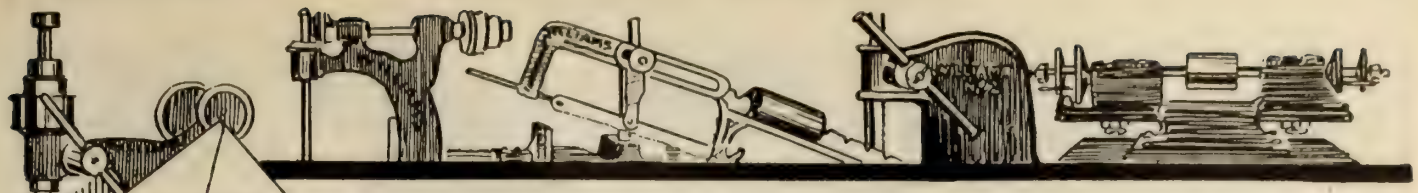
It is reported from Montreal that plans are now under way for the construction of an elevator with a capacity of ten million bushels at that port, and it is likely that building will be commenced this summer. The huge increase in the volume of grain handled in and out of Montreal has made more elevator space essential.

It is thought that in another month the Canadian Locomotive Works will be open at Kingston, Ont. The company was reorganized and grew to its present proportions under the former liberal government. There is a great future for this industry and its future lies in the progressive and constructive policy of the present government.

In common with most other Ontario municipalities Welland is for new industries. There have been some additions during the last year. Industrial Commissioner B. J. McCormick, of Welland, considers that the future in this respect is particularly bright. He finds that American manufacturers are making their plans to take advantage of the revival of business that is expected to begin next Spring. There is a prospect accordingly, that branches of United States plants will be located in good numbers this year and that important steps will be taken by Ontario cities to order industrial expansion.

The concession granted by the Government of Peru to R. W. Dunsmuir, in connection with the construction of a railroad from the Pacific coast to the interior is of no little interest to Canada, inasmuch as Mr. Dunsmuir is the son of a former Lieutenant-Governor of British Columbia, and a coal magnate of that province. The contract will require great quantities of railway construction supplies and equipment, and as there are coal, iron and petroleum areas along the route, a great deal of mining machinery for these special purposes will also be required.

Many lumber concerns in British Columbia report a scarcity of logs and it is stated that there are only about 97 million feet of logs in the water in that province. This figure is said to be the lowest for many years, at this season. It is claimed that the snow which fell in November after a month of rough stormy weather reduced the number of mainland camps to a very low figure. The scarcity of cedar logs is giving the shingle mills considerable worry and shingle manufacturers are investigating to ascertain the quantity of cedar that is going to Japan in the large camp form and in logs. Approximately ten million feet of cedar logs and camp have entered Japan during the first six months of the year from points on the Pacific coast.



According to a recent report a reduction in railroad charges has become effective in Great Britain, this decline being 12½ per cent. and applying to such goods as coal, coke, and patent fuel, lime stone, pig iron, iron and steel in the raw, and semi-finished state. This situation is expected to influence the engineering branches of industry with a corresponding increase of building and manufacturing activity.

Following the collapse of the roof of a Washington theatre recently, engineers in several Canadian cities have been giving considerable thought to the possibility of like accidents to similar buildings here in Canada. It is believed that ample provision has been made in this northern climate for adequate protection along these lines, but as an additional safeguard the authorities are looking into the matter.

In speaking at a banquet recently held at Longueuil, Que., Sir Lomer Gouin Minister of Justice, referred to the proposed bridge, to parallel the Victoria bridge over the St. Lawrence River. In his statement he said: "The construction of this bridge is not only imperative to the Province of Quebec, but to the whole country. It is a measure not only of national but of international importance."

GOVERNMENT MAY BUY "JOHN D. HAZEN"

It has been officially announced that the contract for an ice-breaker placed by the late Meighen Government with Canadian Vickers Ltd., has been cancelled, and that the ice-breaker "John D. Hazen," built by the Vickers Co. in 1914 and sold to Russian Government has been purchased from the French Government, who apparently have obtained title to her. The price to be paid is stated to be £95,000 sterling. It has been ascertained that the vessel, which is now lying at Cherbourg, France, has been surveyed by Lloyds and also that an independent survey has been made by a firm of naval architects and that a full report of the condition of the vessel is in the hands of the Department at Ottawa. Thus a reasonably accurate estimate of the cost of the repairs can be made. Although the reports have not been officially confirmed in the case of the following statements, it is stated that the wear and tear on the steamer and her machinery is negligible but that maintenance has been neglected. Reports vary as to the actual service performed by the steamer and also as to her present state of repair. It is understood that the steamer will have to undergo certain tests at sea at the expense of the French Government before the sale is finally completed. The move on the part of the new government has deprived the local shipbuilding firm of a contract that was expected to very materially help the unemployed in the east end of the city. However, if a very large saving is accomplished for the country, the best course has been taken.

Re-Manufactured Machine Tools

You can save a lot of money buying our used machine tools, because you get machines that have been thoroughly remanufactured and trued-up—machines that are guaranteed absolutely as good as new, much below new prices.

Why pay the full price for a new tool when a much smaller investment will give you equally satisfactory results?

Our name and reputation constitute a guarantee that any machine you buy will be exactly as represented.

If you are interested in receiving our monthly Machinery List, write us and we will put your name on the mailing list.

The A. R. Williams Machinery Co., Ltd.

64 Front St. W. Toronto

HALIFAX ST. JOHN MONTREAL WINNIPEG VANCOUVER

If its Machinery—Write "Williams"

You Received Full Value

It is easy to judge the size and quality of a visible commodity. There are certain recognized standards that have been universally accepted to which purchased articles may be compared.

With invisible commodities, such as a publication's circulation, the matter is not so simple. It was only recently that a definite measurement has been obtained.

The A. B. C. now furnishes a recognized standard by which circulation may be measured. A publication's distribution can now be as accurately gauged as any other purchased commodity.

The Canadian Machinery circulation is measured by the A.B.C. In buying advertising space in its columns you receive dollar-for-dollar value.

THIS IS TO CERTIFY THAT

DEAR COAL COSTS RAILWAY JOBS

JOHN L. LEWIS, president of the United Mine Workers, proposes to the railroad brotherhoods an alliance with his union to fight jointly any and all attempts at wage reductions for members of their organizations. The railroad unions may decide to pool their wage question with that of the coal miners, but if they do they will walk into such an alliance with their eyes wide open as to the enormously important part the cost of coal plays in their own chance to earn a living.

Nobody knows better than the railway engineers and firemen that the fuel they burn under the locomotive boilers is, after labor, the largest single item in railway operating expenses. They know what it meant to roads to have their coal bills go up, as they did go up, from $209,000,000 in 1916 to $673,000,000 in 1920, when nearly eleven cents out of every dollar taken in by the roads went for locomotive fuel.

But this is not all that the cost of coal means to the roads and to the workers on the roads. Nobody knows better than the railway trainmen that the greatest item of railroad traffic in normal times is coal. It is the bulk of the business of most of the carriers in the United States. But even this is not all that coal means to the railroads and their workers. If the coal bills of the carriers were up from $290,000,000 in 1916 to $673,000,000 in 1920, think how the coal bills of the industries of the country went up in the same time on annual consumption of between 500,000,000 and 600,000,000 tons!

When coal is hauled in its normal volume it makes harder work for all railroad men, not only because of the coal haulage itself but because of the haulage of products from industries to which the coal goes for power. But when the cost of the coal is excessive, as it is now, the volume of coal haulage falls to a low-water mark, where it is now, because thousands of productive industries cannot operate at a profit with prohibitively dear fuel. When coal shipments to those industries run down or stop, and in consequence return freights from those industries run down or stop, train crews that must go off the railroad payrolls all over the country number tens of thousands.

When nobody has a bigger stake than the railroad workers in cheap enough coal to enable American industries to turn out freight for the American transportation system to haul, the hard headed railway brotherhood chiefs may think twice before they form an alliance with the coal miners to keep the price of fuel so high that it will cost railroad workers their jobs, as it will cost the coal miners their jobs, just so long as the price of coal does not come down where it needs to be to permit industrial America to do business on the American scale.—From New York World.

New Catalogues

The Cleveland Electric Tramrail division of the Cleveland Crane & Engineering Co., Wickliffe, O., is circulating an illustrated folder in which an electric tramrail system is illustrated. The illustrations show the use of this overhead system of trucking in a number of actual installations.

The Bickford-Switzer Co., Greenfield, Mass., has published a 4-page leaflet in which a newly designed counterbore is described. This new counterbore has two lips, ample clearance and spiral flutes. The body is circular between the cutters. Sizes carried in stock by the company are given.

An 8-page illustrated booklet has been published by the Sprague Electric Works of the General Electric Co., Schenectady, N. Y., in which electric dynamometers are described and illustrated. These dynamometers are built in a number of sizes, varying from a nominal rating of 2 horsepower at 1,000 revolutions per min., to a nominal rating of 500 horsepower at 1,000 revolutions. All sizes have a wide range of speed above and below their rated values. They are adapted for testing both high and low speed apparatus.

A bulletin pointing out the dangers incidental to the freezing of fire extinguishing equipment has been issued by the National Fire Protection Association of Boston. It is stated that a very small "freeze-up" may destroy the efficiency of a large installation, and that constant vigilance is required to avoid temporary disarrangement of the system. Emphasis is laid on the necessity of all manufacturing plants taking early precaution to protect such equipment against the possibility of freezing.

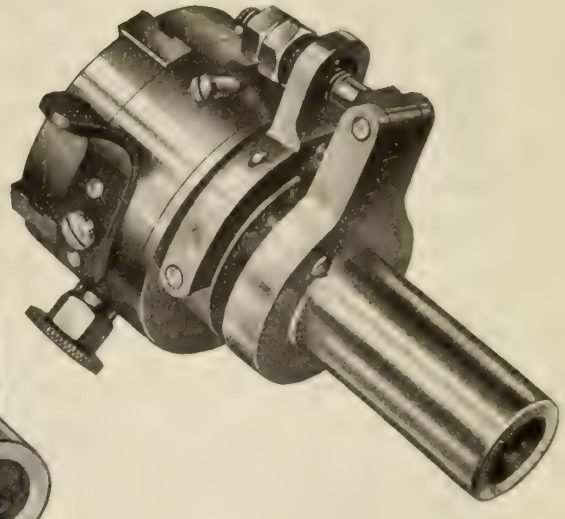
The High Mark In Screw Cutting



The Geometric Style DS Die Head touched High Mark in popularity at a time when Buying was at Low Mark.

Self-Opening!
Adjustable!
Reliable!

It Fills the Requirements —That's the Reason

Brown & Sharpe Automatics, as well as other single spindle machines, needed just such a Screw-Cutting Die Head—and the Geometric DS is it. With a DS Die Head on the machine there is:

No reversing of the spindle to back the Die Head off the threaded work.

No stripping and shaving of threads, for the Die Head floats to suit the thread being cut, and does not depend on the turret feed.

No burden of tripping the Die Head, because of the easily adjustable lever trip, which lightens the reaction on the threads as they are cut.

No shock and wear, even when closing the Die Head rapidly, because of the spring closing attachment.

No face plate necessary, allowing the use of projecting chasers when cutting is close to shoulder.

No cutting of taper threads for the chasers have long bearings in the Die Head skeleton and are supported by hardened keys, which prevent tilting.

Consider the economy of these Die Heads with micrometer adjustment, over the use of a button die with no adjustment.

Geometric Die Heads are sent on trial to reliable concerns.

SPECIAL OFFER of MACHINE T

SHAPERS

No.
1046 1—Gould & Eberhardt 20″ Shaper, complete with vise.
1097 1—Smith & Mills 15″ Shaper, complete.
653 1—McGregor-Gourlay 24″ Shaper, complete.

MILLING MACHINES

673 1—Ryerson Owen No. 3 Universal, complete.
671 1—Briggs, Type A, 22″ traverse, Manufacturing Miller.
2089, 1050, 1062 3—Chicago Pedestal type, Hand Millers.
2088, 2088A, 618 3—Standard do
1061 1—Garvin No. 2 do
1072 1—Barber-Coleman No. 3 Thread Miller.
1074 1—Hendey No. 4 Plain Miller with vise and dividing head.
2075-2086 11—Burke No. 1 Hand Millers, bench type, table 12″x3½″.
2087 1—Toledo Hand Miller, table 23″x5″.
876 1—Plain Dividing Head for No. 3 Miller.
877 1—Vise for Milling Machine.
1055, 1056 2—Pratt & Whitney 4½″x12″ Thread Millers, with C/S.
642 1—Castellating Attachment for Miller.

BENCH LATHES

1029 1—Hardinge (Cataract) 7″x32″ Bench Lathe, with head and tailstock, compound rest, plain rest.
734 1—Hardinge (Cataract) 7″x32″ Bench Lathe, with head and tailstock, compound rest, plain rest, chasing attachment.

PRODUCTION LATHES

2005-2012 8—LeBlonde 17″x8′ Heavy Duty with C/S.
1098-2004 6—LeBlonde 17″x6′ Heavy Duty with C/S.
2013-2016 3—LeBlonde 17″x6′ Rapid Production, with C/S.
2017 1—Reed 14″x6′ Extra Heavy Duty, with C/S.

TOOL ROOM LATHES

1075 1—C.M.C. 16″x6′, chuck, face plates, C/S.
1083 1—Hendey 14″x6′, S.B.G., Q.C.G., chuck, face plates, C/S., taper attachment.
1078 1—Monarch 14″x6′, D.B.G., Q.C.G., chuck, face plate, C/S., taper attachment.

PLANER

1089 1—Bertram 30″x30″x8′, single head on rail, worm drive, motor driven, vise.

HACK SAWS

891 1—Racine No. 10, 8″x8″.
661 1—Peerless, 6″x6″.
951 1—Perfect No. 3, 6″x6″.
881 1—Millers Falls, 6″x6″.

TURRET LATHES

1036 1—Small Foster-Kimball, C/S.
1031-1040 4—No. 3 Foster, capacity 1⅝″ in spindle, C/S.
1041-1044 4—No. 2 Foster, capacity 1 1/16″ in spindle, C/S.
2023-2043 20—16″x6″ Bliss Heavy Duty.
2044-2054 10—No. 2 Foster with round turret, capacity 1 1/16″ in spindle, C/S.
2055-2060 5—No. 3 Foster with round turret, back geared, capacity 1⅝″ in spindle, C/S.
2061-2065 4—No. 3 Foster, with hexagon, turret, back geared, capacity 1⅝″ in spindle, C/S.

No.
2066 1—J. & L. 15″ Turret, round turret, 1¼″, hollow spindle.
2067 1—16″x6′ McGregor-Gourlay Turret Lathe.
2068 1—18″x6′ McGregor-Gourlay Turret Lathe.
2069 1—20″ No. 4 Bullard with hexagon turret.
2070, 2070A 2—16″ Warner & Swasey, Geared Head.
2073 1—17″x6′ Davis Lathe with round turret.
819 1—Oliver 18″ Turret with C/S.
818 1—B. & O. 16″ Turret with C/S.
815, 816 3—Davis 24″ Turret Lathes with power cross feed.

GRINDERS

590 1—Bench Type Double End, two-step cone pulley on spindle, no C/S.
1067 1—Bench Type Double End, single pulley on spindle, no C/S.
1068 1—Woods Eng. Co. No. G265 Tool Grinder.
1069 1—Gardner No. 24 Grinder.
1070 1—Double End Emery Grinder on pedestal, two-step cone pulley on spindle, 1″ diameter spindle, C/S.
1071 1—Double End Emery Grinder, on pedestal, single pulley on spindle, 1″ dia. spindle, C/S.
1079 1—Wells Tool Room Grinder.
1095 1—Walker 6″x36″ Surface Grinder, complete with all attachments.
2109, 2110 2—Perfect No. 6 Pedestal Grinders.
2117 1—Sellers 5/16″x3″ Drill Grinder.
939 1—Landis 12″x42″ Plain Grinder.
890 1—Globe Universal Tool Room Grinder.
898 1—Lafayette Universal Motor Driven Tool Grinder for lathe work.
640 1—Double End Pedestal Emery Grinder, two-step cone pulley on spindle, C/S.
1064 1—Symington Plain Grinder, C/S.

GAP LATHES

656 1—C.M.C. 20″x38″x12′, D.B.G., Q.C.G., face plate, chuck, C/S.
1091 1—McDougal 20″x6″x12′, chuck, face plates, C/S.

DRILLS

1048 1—Barnes 15″ Sensitive.
1065 1—Perfect 14″ do
1066 1—Mechanic's 24″ B.G. Drill Press.
1085 1—Perfect 15″ Sensitive.
1088 1—Langelier 10″ Bench Type with C/S.
1096 1—Ford Smith 22″ Back Geared Drill Press.
1086, 1087 2—Rego Bench Drills with Nerlington tapping device, ⅜″ cap.
2074 1—Colburn D-1 High Speed Heavy Duty.
947 1—Silver 3 Spindle 20″ Gang, one spindle with tapping attachment.
945 1—Edlund 15″ High Speed Ball Bearing Drill Press.
839 1—Fosdick No. 2½ Radial Drill.
675-678 4—Woodward 4 Spindle Drill Presses.

SCREW MACHINES

1057, 1058, 1059 3—Acme No. 55 4 Spindle Automatics.
1093, 1094 2—Garvin No. 1 Wire Feed, C/S.
2071, 2072 2—Warner & Swasey No. 6 with geared head, automatic chuck, C/S.
1018 1—Warner & Swasey No. 1 Screw Machine.

ENGINE LATHES

1047 1—Cincinnati 16″x8′, D.B.G., screw feed, chuck, 2 face plates, C/S.
1049 1—American 18″x6′, S.B.G., rod feed, chuck, 2 face plates, C/S.
1073 1—LeBlonde 17″x6′, S.B.G., Q.C.G., rapid production, rod feed, chuck, face plate, C/S.
1076 1—Pratt & Whitney 10″x4′, S.B.G., rod feed, chuck, face plate, C/S.

1081 1—LeBlonde 16″x6′, S.B.G., Q.C.G., chuck, face plates, screw feed, C/S.
1082 1—Hamilton 16″x8′, S.B.G., Q.C.G., screw feed, chuck, face plates, C/S.
1084 1—Davis 12″x6′, S.B.G., Q.C.G., chuck, face plates, C/S.
1092 1—Reed 16″x7′ Plain Lathe, S.B.G., no feed, head and tailstock only, good for wood turning.
2018 1—Stevens 16″x6′ Engine Lathe, screw cutting, C/S.
2019 1—McGregor-Gourlay 16″x7′ Engine Lathe, screw cutting, C/S.
2020 1—Stevens 16″x8′ Engine Lathe, screw Cutting, C/S.
2021 1—Stevens 18″x8′ do
2022 1—Lodge & Davis 18″x8′, screw cutting, with C/S.
812 1—Putnam 36″x18′, S.B.G., screw cutting, face plates, C/S.
810 1—McKechnie-Bertram 20″x10′, S.B.G., face plates, C/S.
809 1—McGregor-Gourlay 18″x12′, S.B.G., face plate, C/S.
666 1—Rae 18″x8′, D.B.G., Q.C.G., face plate, C/S.
639, 643, 646 3—Speed Lathes.

BUFFING MACHINES

1051-1054 4—Perfect 36″, Pedestal Type, 1¼″ spindle.
627 1—24″ do 1″ spindle.

TAPPING MACHINES

1063, 1086, 1087 1—Ricker Schaefer ⅜″, friction feed.
733 2—Rego Bench Drill Type Tappers, ⅜″ capacity.
602 1—Burke Bench Type, horizontal, ¼″ capacity.
1— do ¾″ capacity.

PRESSES, PUNCHES AND SHEARS

1035 1—Brown-Boggs No. 90 Kick Press.
944 1—Greenerd No. 3½ Arbor Press.
742 1—Niagara No. 3 Arbor Press, pedestal type.
741 1—Niagara No. 3½ Arbor Press, pedestal type.
761 1—Laurie No. 19 Punch Press.
822 1—Stiles No. 172 Punch Press.
1020 1—Bench Type Punch.
1021 1—Bench Type Shear.
2108 1—Toledo No. 57½, Back Geared, Power Press, 4 tee rods, 12″ stroke, 140-ton capacity, 6″ crank shaft, 24½″ between uprights, weighs approximately 35,000 lbs.
Also a number of Bliss and Brown-Boggs Inclinable Presses.

BLOWERS

A number of Buffalo, Sheldon, Root Blowers of varying sizes and capacities.

PUMPS, ACCUMULATORS

884 1—Vertical, 2 plunger, hydraulic, 2½″ dia. x 6″ stroke, 1¼″ inlet and discharge.
813 1—Northey Duplex, 6″x4″x7″.
780 1—Goldie-McCulloch, 2″ suction, 1½″ discharge.
779 1—Smart-Turner 4½″x2¾″x6″.
2090 1—West Tire No. 3, 2 cylinder plunger pump.
2091 1—Gould Triplex Plunger Pump.
2092 1—Perrin Triplex Plunger Pump.
2093 1—Small Size Two Plunger Pump.
2119 1—Hydraulic Accumulator, 6″x8′ ram, capacity 10 imperial gallons, 1,500 lbs.
2137-2147 A number of Lubricating Pumps for use on Lathes, etc.

MOTORS AND ELECTRICAL EQUIPMENT

830 1—C.G.E. Generator Set, type, A.P.B., class 8-125-900 K.V.A., 125-575 volts, 3 phase, 60 cycle, 125-5 amps., 900 r.p.m., complete with 1—5 H.P., D.C., Exciter, type M.L.4-5, 40 amps., 125 volts, speed 1,800 r.p.m
1—Switchboard, type ATG-64-150 amps, 600 volts, complete with rheostat, voltmeter and ampere meter.
835 1—Can. Allis-Chalmers 5 H.P., 3 phase, 25 cycle, 550 volt, with base and pulley.
1031 1—Lincoln 20 H.P., 3 phase, 60 cycle, 220 volts, 1,200 r.p.m., with base and pulley.
660 1—Tor. & Ham. 12 H.P., 3 phase, 25 cycle, 220 volts, 1,500 r.p.m., with base and pulley, no starter.
634 1—Can. Allis-Chalmers, 5 H.P., 3 phase, 60 cycle, 550 volts, 1,200 r.p.m., with base and pulley.
1090 1—Chapman Walker 20 H.P., 3 phase, 25 cycle, 550 volts, with base and pulley.
2094 1—Robins & Myers ½ H.P., 3 phase, 25 cycle, 550 volts.
2095 1—Robins & Myers ½ H.P., 1 phase, 25 cycle, 110 volts.
2097, 2098 2—Westinghouse 50 H.P., 3 phase, 25 cycle, 550 volts, with base and pulley.
2096 1—Chapman Walker 40 H.P., 3 phase, 25 cycle, 550 volts, 750 r.p.m., with base and pulley.

MISCELLANEOUS

2099-2102 3—Strong-Carlisle-Hammond Continuous Annealing Furnaces, 22″ long x 3′x2½′ opening.
2103-2106 3—Strong-Carlisle-Hammond Furnaces for heating drop forge work.
2107 1—Lead Annealing Furnaces, pot space 20″x24″ deep, for gas or oil burners
2128-2136 8—Singer Factory Sewing Machines.
2127 1—Brown Pyrometer, 2000° Fahr.
2148 1—Heavy Double Galvanizing Iron Tank, inside dim. 4′3″ long, 2′6″ wide, 2′6″ deep, outside dim. 5′3″ long, 3′6″ wide, 3′ deep.
2149-2150 2—2″ Cypress Wood Plating Tanks, inside dim. 5′8″ long, 20″ wide, 20″ deep.
2151-2152 2—2″ Cypress Wood Plating Tanks, inside dim. 3′ long, 18″ wide, 18″ deep.
2153-2154 2—Southwark Hydraulic Physical Testing Presses, 2,000 lbs per sq. in. pressure, 2 column type fitted with intensifier ram, revolving table guard and suitable drain basin, mounted on pedestal and arranged for single lever control.
2155 1—Metalwood Hydraulic Testing Press similar to above.
1032 1—Jardine No. 50 Power Hammer.
1030 1—C. B. & [illegible]. No. 734H Blacksmith Forge.
1019 2—Sand Riddles.
946 1—Bellevue Oil Furnace.
888 1—Gas Furnace, 12″x15″x8″, two burners, size of door opening 10″x8″.
848 1—Ham. Motor 6″x6″ Double Cyl. Air Compressor with 6′ tank.
841 1—One Ton Portable Crane.
840 1—Two Ton Portable Crane.
689 1—Gas Furnace, 18″x11½″x8″, 2 burners, door opening 10″x8″.
605 1—Sand Blast, 30″ dia. x 36″. long, complete with attachments.
2111-2114 3—Bertram Stenciling Machines.
2115 1—Holden Morgan Stenciling Machines.
2116 1—Burring Machine.
2118 1—Four Pt. Tapalog complete (Wilson-Maulin).
2120-2123 3—Brantford Counter Scales.
2124-2125 2—DeVilbiss No. 13 S.M. 152 Internal Varnishing Machines.
Quantity of Wood Split, Steel Split Pulleys, Hangers, Belting, various sizes.

INERY, LIMITED

Montreal Branch: 356 Hingston Ave.

Classified Opportunities

MACHINERY WANTED

THE FOLLOWING MACHINERY IS WANTED by one of our foremost technical schools:—
5 lathes, 6 ft. bed, 14 inch swing (one of these will be a tool room lathe with quick change gears).
1 16-inch shaper,
1 drill press,
1 Universal milling machine,
1 power hack saw,
forges, anvils, vises,
1 combination cut off and rip saw,
1 band saw,
1 tool grinder,
1 glue stand,
1 electric glue pot,
1 pony planer,
3 wood turning lathes of different sizes, all machines to be motor driven,
1 blue print machine.
Please address all replies to Box 862T. Canadian Machinery.

WANTED — A LATHE AND GEAR CUTTER. Must be in good condition. Advertiser desires to get in touch quickly with any person who is able to offer same. Apply Beaver Machine Shop, 1110 Center St., Calgary, Alberta. (c5mlg)

MACHINE WORK WANTED

MACHINE WORK WANTED FOR LATHES, shapers, milling machine and planer, etc. Hourly or contract basis. Prompt delivery. W H Sumbling Machinery Co., Toronto. (etfm)

EQUIPMENT WANTED

CAFETERIA EQUIPMENT — RANGE, STEAM table, glass shelving, urns, Cash register, etc. Must be in first class condition. Give description and prices. State where may be inspected. Box No. 801L, Canadian Machinery.

Machinery Wanted

Advertisements under this heading will be inserted once free of charge. Readers are invited to use this department when in need of equipment. Replies may be sent to box number, care of Canadian Machinery, if desired.

REGO WELDING *and* CUTTING APPARATUS

Oxygen, Acetylene, and a complete line of Welding and Cutting Supplies

Carter Welding Co.
of Toronto, Limited
7-11 Sheppard St., Toronto, Ont.
Phones: Adelaide 2841 and 1524
(TF)

Modern Marine Machinery

Automatic Steam Towing Machines, Ship Windlasses, Cargo and Deck Winches, Steam Capstans, Dock Gypsies, Steering Engines, Hydraulic Freight Hoists, etc. Grey Iron and Brass Castings. Special machinery built to order. The Corbet Foundry & Machine Co., Limited, Owen Sound, Ont. (52)

CLOSING TIME

Advertisements for this section must be in our composing room Tuesday morning prior to day of issue.

In order that the announcements of your wants, machinery for sale, etc., etc., shall not be delayed, please try to have them in our office with the Tuesday morning mail.

Canadian Machinery

SITUATIONS WANTED

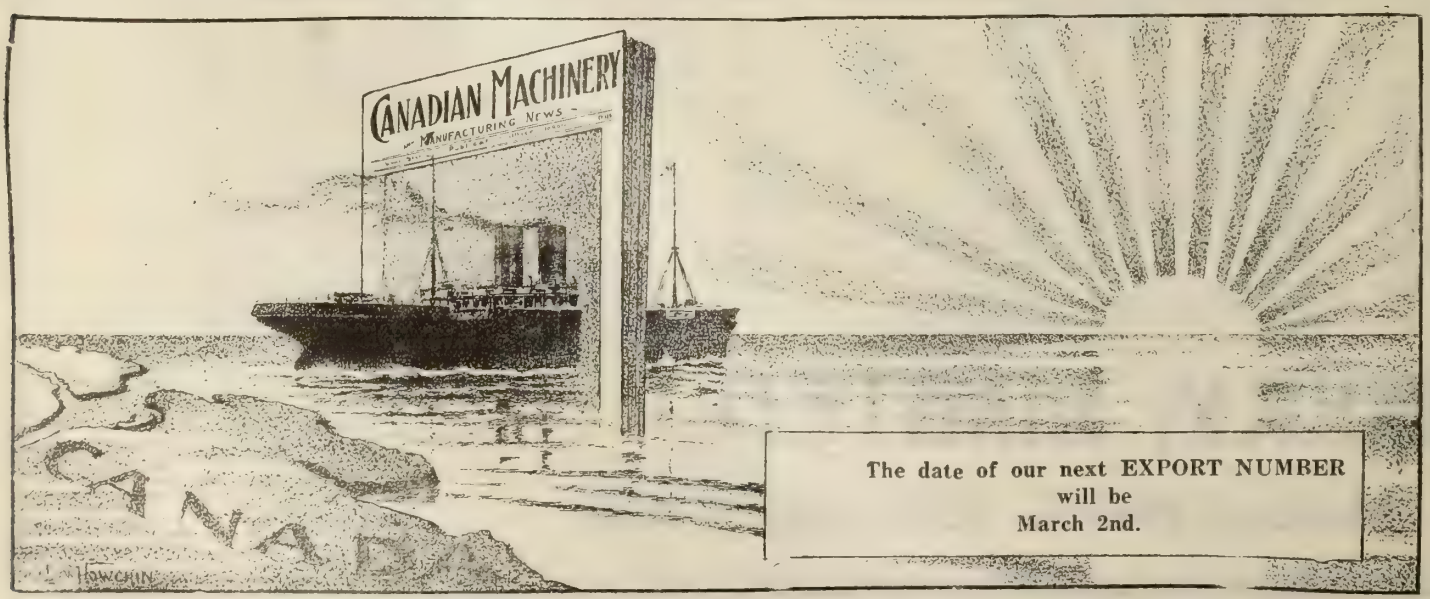
SITUATION WANTED AS SUPERINTENDENT or general foreman of machine shop, twenty years' experience. At present employed; best of references. Box 861T. Canadian Machinery. (c23m)

AGENCIES WANTED

IF YOU ARE LOOKING FOR A HIGH-GRADE firm to handle through the hardware jobbers and consuming trade throughout the Dominion, write us. It will be worth your while to investigate the special features of our marketing proposition. We know what co-operation means. Write to Box 860T., Canadian Machinery.

BUSINESS CHANCES

WANTED—BY AN ESTABLISHED CONCERN. Twelve to fifteen thousand dollars for a period of from one to three years, to take care of business expansion. This concern will stand the fullest investigation. 8% is offered with ample security to principals only, with an opportunity of becoming permanent associates with the partners, if mutually satisfied. Box 767, Canadian Machinery. (etfm)



PATTERNS

TORONTO PATTERN WORKS, 65 JARVIS Street, Toronto. Patterns in wood and metal for all kinds of machinery. (etfm)

BRANTFORD PATTERN WORKS ARE PREpared to make up patterns of any kind—including marine works—to sketches, blue prints or sample castings. Prompt, efficient service. Bell 'Phone 631; Machine 'Phone 733. Brantford Pattern Works, 49 George St., Brantford, Ont. (ctfm)

Grey Iron Castings

Light and Medium-Bench and Floor Repetition Castings; Capacity 15 tons per day.
Expert Metal and Wood Pattern Work. Our advice and estimates will save you money.
Semi-finishing operations on Lathe or Grill on Castings supplied if required.
ASK US.
THE KATIE FOUNDRY, GALT, ONT.

The date of our next EXPORT NUMBER will be March 2nd.

THE

TRADE K—T IE MARK

FOUNDRY
GALT, ONT.

Do Your Castings Cost Too Much?

A rearrangement of your patterns might cut their cost 25 per cent.; a different method of molding them might double your production at no increase in molding cost. We can advise you and we have expert metal and wood patternmakers who are able to make any changes that may commend themselves to you.

If you need some new Patterns

send us a sample, blueprint or sketch, and ask for our advice. It won't cost you anything. If our advice is good and commends itself to you, it is only fair to assume that our work will be equally satisfactory, and we need the work as badly as you need the patterns.

We are in a position to do turning, boring, drilling or other semi-finishing operations on castings supplied by us. Ask us.

We have for our and your requirements, a large stock of assorted White Iron Stars, suitable for light agricultural to medium weight machinery castings, while they last, at 8 cents per lb. F. O. B. Galt.

Canadian Machinery BUYERS DIRECTORY

If what you want is not here, write us, and we will tell you where to get it. Let us suggest that you consult also the advertisers' index—last page of book, after having secured advertisers' names from this directory. The information you desire may be found in the advertising pages. This department is maintained for the benefit and convenience of our readers. The insertion of our advertisers' names under proper headings is gladly undertaken, but does not become part of an advertising contract.

List of Directory of Dealers will be found above Advertising Index

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

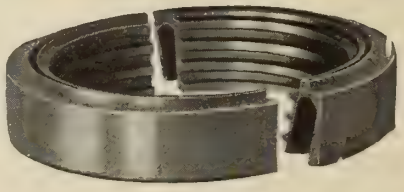
Jacobs Super Chuck

Patented 1909-1915. Other patents pending

A Look Inside



Here are the several parts—carefully designed, exactly fitted, perfectly made—that guarantee the Jacobs Super Chuck to hold a drill tight, to hold it right, and to keep on doing its work indefinitely.

FIRST THE BODY—scientifically casehardened; size limits within .0005″, arbor hole ground on a special fixture with six gauges to position it accurately in relation to the hole for the jaw.

THE SLOT FOR THE NUT, correctly located in relation to the jaw holes by means of micrometer gauges, insures a properly fitting thread on the nut and jaws.

NO WEAR ON KEY HOLES because of the deeply casehardened body, result—a well-fitting Gear on Sleeve and Key.

THE JAW, OF TOOL STEEL, has glass hard gripping surface; threads are tough, and all surfaces are ground on centers to within **a quarter of a thousandth** of an inch.

THE NUT, of special analysis steel, is ground after heat-treatment, in correct alignment with thread; tolerance .0005″.

THE BALL RACE comes within limits of .0001″; finest grade balls are used. An important point is the pitch of thread on nut—angle is 90 degrees to center line of jaw, so part cannot run over thread of latter.

The Jacobs Super Chuck centers a drill, **accurately,** and will continue to do so after years of use. It saves its cost time and again by preventing drill breakage. Its correct balance preserves bearings of your drilling machine—order a Super Chuck from your dealer.

You Need a Good Die Stock Set

If you need one at all.
Because a **GOOD** Die Stock Set embodies:

1. Accuracy in its product.
2. Adjustment for wear.
3. Free cutting qualities.
4. Provision for sharpening.
5. Ample adjustment for oversize or undersize.

P. & W. Die Stock Dies **ARE GOOD DIES.**
BETTER than most because of the interchangeable feature in their chasers. A broken chaser in a P. & W. Die doesn't mean a new set of chasers. You can get a new chaser to replace a breakage and the new one "fits in" perfectly in your old set. That's the 6th point, **"ECONOMY IN OPERATION."**

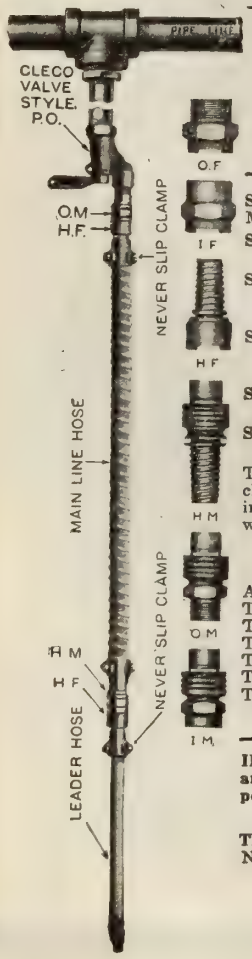
For Making Perfect Screw-Thread Joints

SMOOTH-ON
ELASTIC CEMENT NO. 3

A screw-thread joint made with Smooth-On Elastic Cement No. 3 will not leak, because the Smooth-On expands in metallizing and so closes up any defective places which otherwise would cause leaks; yet the joint may be taken apart when desired.



Smooth-On Elastic Cement is sold ready for use in paste form. It is applied to the screw-threads with a brush. Especially useful for high pressure steam or water joints, for ammonia joints, for coating flanged joint faces and for coating gaskets.

Send for our new Smooth-On Instruction Book No. 18. It illustrates and describes how to make perfect screw-thread joints and hundreds of other repairs. You will marvel at its contents. The book is **FREE.**

Cleco Pressure-Seated Air Valves

Bowes Air Hose Couplings—Cleco Never Slip Hose Clamps — Cleco Grooved Hose Nipples and Hose Clamp Tool

STYLE O.F. is an Outside Thread Female Pipe End. Made in sizes ⅜-inch to 1½-inch.

STYLE I.F. is an Inside Thread Female Pipe End. Made in sizes ¼-inch to 1½-inch.

STYLE H.F. is a Female Hose End with spiral shank to insert into the hose and has groove for the Never Slip Hose Clamp. Made in sizes ¼-inch to 1½-inch.

STYLE H.M. is a Male Hose End with spiral shank to insert into the hose and has groove for the Never Slip Hose Clamp. Made in sizes ¼ inch to 1½-inch.

STYLE O.M. is an Inside Thread Male Pipe End. Made in sizes ⅜-inch to 1½-inch.

STYLE I.M. is an Inside Thread Male Pipe End. Made in sizes ¼-inch to 1½-inch.

The Male and Female Ends of Bowes Couplings interchange in sizes ¼-inch to ¾-inch. Sizes 1-inch and 1¼-inch interchange. The 1½-inch ends interchange only with themselves.

BOWES COUPLINGS

Are instantly connected or disconnected.
They are absolutely air-tight under all pressures.
They quickly pay for themselves by stopping costly leaks.
They interchange in sizes most commonly used.
They have no loose parts to be mislaid or lost.
They are made of brass and will not rust.
The U-shaped Gasket interchanges in couplings ¼-inch to ¾-inch.

CLECO AIR VALVES.

Style R.A. Style P.O. Style A.

Style P.O.—Made in sizes ¼ in., ⅜ in., ½ in., ¾ in., 1 in., 1¼ in., 1½ in., 1¾ in., and 2 in. Pipe Outlets. Inlets are one pipe size larger.
Style A—30° Angle Valves, are made in sizes ½ in., and ¾ in.
Style R.A.—Right Angle Valve, made in sizes ¼ in., ⅜ in., ½ in., and ¾ in.

CLECO GROOVED HOSE NIPPLES

Grooved Nipples when attached to the Hose with Wire Clamps as illustrated cannot "blow out." Wire clamp tool shown below applies the wires to hose.

The Lighting Hose Clamp Tool illustrated applies wire clamps at a cost of 1½ cents each.

Use Annealed Wire No. 14

In stock: Riveting and Chipping Hammers, Air Drills, Emery Grinders, Sand Rammers, etc.

IMPORTANT:—The Small Leaks in your "AIR LINE" mean serious loss in DOLLARS. Have you any idea of the amount of "Air" wasted in small leaks at your connections? Air Leakage through 1-16 in. opening equals 5.32 cu. ft. per minute at 80 lbs. It will pay you to install Bowes Couplings and Cleco Valves, which will stop costly leaks.

Bulletin No. 50, mailed on request.

THE MODEL HOSE LINE illustrated shows correct styles of couplings and valve to use and proper way to attach the Cleco Never Slip Hose Clamps to Bowes Couplings. No "blow-offs" can occur when "Cleco" Clamps are used.

WHAT IS YOUR ADVERTISING DOLLAR BUYING?

High prices of materials and increased overhead have made necessary a stricter economy along mercantile lines.

Advertising should be considered as well as the commodities in which merchants deal. By choosing only those publications whose circulation is accurately measured, you not only practise economy in your advertising, but are assured that your money is buying a definite quantity of circulation.

Canadian Machinery's circulation is measured by the Audit Bureau of Circulation. Advertising placed in its columns is an economical investment.

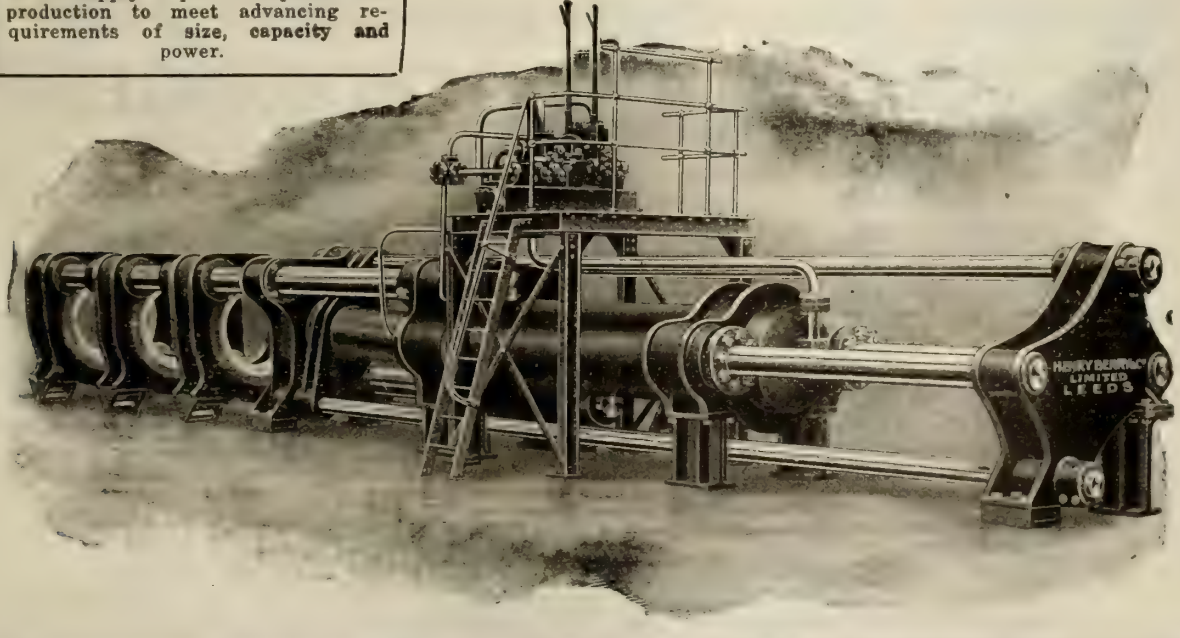
LEEDS, England

Codes: A.I., A.B.C.(5th Edition), Engineering, Everybody's Pocket Code, Marconi International.

CANADIAN AGENTS:

Messrs. Fairbanks-Morse Company, Limited.

***Head Office*—Montreal**



A Cradle Of Imperial Industry

Concerned for many years with the design and the manufacture of some of the largest types of machinery for the British Government, the Colonies and the Indian Empire, the firm of Henry Berry & Co. possesses some of the most extensive resources in the country for the production of the biggest, most powerful and most practical types of hydraulic machinery for Shipyards and Industrial Enterprises. These include all kinds of Shipyard Tools, Plate and Armour Bending Rolls, Rivetters, and Punching and Shearing Machines, Presses and Cranes.

Designs and estimates will be submitted to all requirements without charge. Prompt deliveries with full guarantee of Quality and Power.

750 TON PUNCHING & DRAWING PRESS

Pioneer manufacturers of hydraulic shell forging presses for the largest shells in use during the Great War, we are likewise always to the fore in the supply of plant for peace time production to meet advancing requirements of size, capacity and power.

BETTER TOOLS MAKE BETTER WORKMEN!

And there are no better tools of their kind than WILLIAMS' Superior Drop-Forged Hammers. All kinds, all sizes.

OXYGEN
Facilities for Service that are unassailable
When you order "Liquid Air" Oxygen or Dissolved Acetylene it is delivered to you at the very time you want it delivered, with no exorbitant costs added for freight or long distance haulage. This is only made possible by "Liquid Air" chain of factories situated at convenient centres all over Canada, operating in conjunction with service stations situated at a point in your own immediate neighborhood.
Wherever your plant or workshop is situated you have a constant supply of Oxygen and Acetylene immediately available and Liquid Air service demonstrators are at your disposal at all times to help and advise you on all matters pertaining to the Oxy-Acetylene Process.

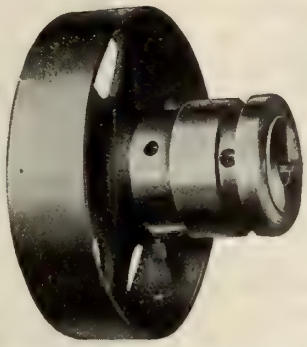
THE JOHNSON FRICTION CLUTCH

Friction Clutches From Stock



Johnson Clutches, both single and double, can now be obtained from stock in our standard slow speed type to fit all common shaft diameters and all standard pulley bores, within the range of light and medium horse powers that we cover.

State definitely —

Just what the clutch must drive.
Actual maximum horse power.
Speed of clutch shaft.
Diameter of shaft.
Diameter, width and bore of pulley.

We Will Select the Proper Clutch and Make Immediate Shipment on All Ordinary Requirements.

Friction Control Means Better Machinery

And the Johnson Clutch is supreme among friction clutches. Adopt it as your standard — always dependable and always promptly obtained.

Complete engineering service to consult on your problems and to handle special installations of any kind.

KEMPSMITH

No. 2 UNIVERSAL

Thirty-two years ago the Kempsmith Company began its career in a small one-storey frame building. To-day there are four main buildings, aggregating 106,000 square feet of floor area, besides various storage sheds, etc. Every building of the plant is a model of its kind.

It has always been, and will continue to be, the purpose of the Kempsmith Company to produce machines of the highest quality only, suited to the most advanced practice.

Every machine, whatever size or type, is put to test under cuts and conditions purposely more severe than it will encounter in even the most progressive shops, and when it leaves our factory it has our positive and definite guarantee back of it.

Literature will be gladly sent upon request.

Empty Shelves— and a Prediction

WITH inventories completed, retail hardware merchants find their stocks smaller now than at any time in recent years. Merchants have held back on spring bookings and freely admit that present stocks are totally inadequate for "Spring and Summer" trade.

Reports from retailers in all parts of Canada are such that we predict a pronounced buying movement within the next six weeks. We are entering a period of improved but cautious buying activity. Purchases will be considered more carefully, comparisons will be made more freely than heretofore. Merchants are adopting a "convince me" attitude. Unknown houses and unknown products are going by the boards these days. Merchants are not taking chances on buying any lines where there is an element of doubt as to the standing or reliability of the manufacturer or the product.

Merchants are the "choosers" to-day. The question is not one of where can I secure goods? It is a question of "whose line will I stock?" At the moment of decision, the line consistently advertised in Hardware and Metal—all other things being equal—is the one that stands the best chance of acceptance by the merchant. The 34th Annual Spring Buying and Directory Issue of Hardware and Metal, reaching the trade on March 18th will be studied closely by over 95% of the most important wholesale and retail hardware buyers across Canada from coast to coast. Thousands of feet of empty shelving will be filled up with lines advertised in the 34th Annual Spring Buying and Directory Number. Reservation should be made immediately.

BROWN & SHARPE

PLAIN GRINDING MACHINES

A New Angle on the Economy of Grinding

Quantities of jobs demanding high accuracy and smooth finish, now being completed on automatics and turret lathes, can be finished with greater economy by grinding. Let's see how this is so. By giving pieces an allowance for grinding, you increase production on your automatics and turret lathes, no longer holding them to the slower speeds and feeds necessary for high accuracy or smooth finish.

The grinding machine keeps pace with this increased production and turns out smoother, more accurate work than could be secured by other methods. Thus quantity is increased and quality improved by the use of grinding machines.

Perhaps these points have thrown more light on the economy of grinding. The Brown & Sharpe No. 11 Plain Grinding Machine shown above is a popular size for production work.

VOL. XXVII. No. 8 FEBRUARY 23, 1922

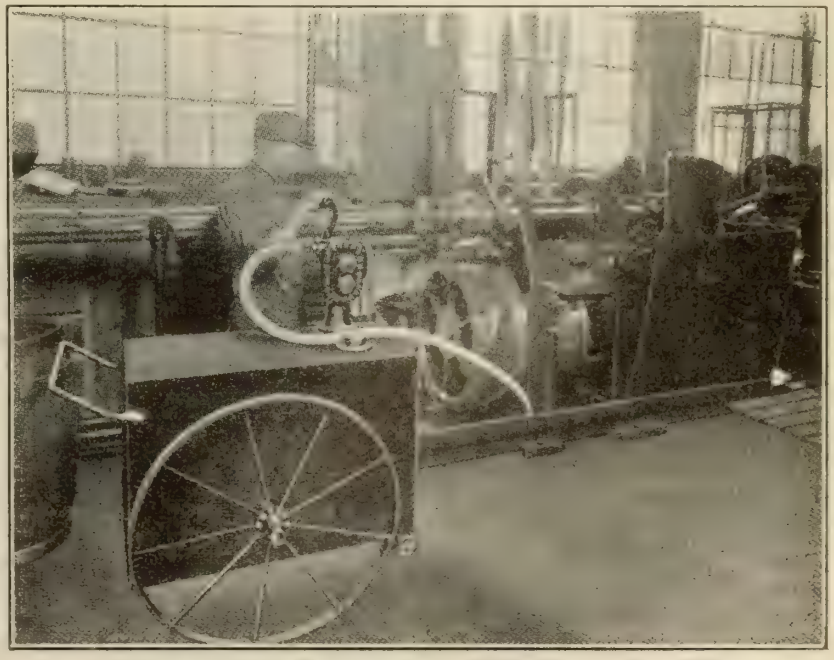
Reducing Expense by Careful Oil Supervision

Economy of Closed Tank—Machinery Depreciates When Poor Oil is Used—Lubricant For Varied Uses—Proper Facilities Required for Oil Storage—Saving Fuel and Power

By WADE HAMPTON, Jr.

THERE is no more vitally important item in connection with the operation of machinery than lubrication, and by lubrication I mean, not the squirting on indiscriminately of oil, but of applying to each individual unit of a manufacturing plant, or each different unit of machinery, a correct and scientifically perfect oil for that particular unit.

As the human body must be properly fed, nourished and cleansed, so must machinery be properly nourished, fed and kept in an absolutely clean condition. It is just as sensible to suppose that you can feed a horse saw-dust instead of corn or oats and expect him to do as much work as a properly nourished horse would do, as it is to expect improper lubrication to produce 100 per cent. efficient lubrication. More money is wasted every year by operators of machinery on account of the poor or improper grade of lubricating oil they use, than on any other article that is necessary for the operation of manufacturing and power plants.



In a considerable number of years of visiting manufacturing plants, power generating stations, etc., the writer has had occasion to observe a great many conditions in connection with the lubrication of such plants which indicate that very little thought is given to the subject of correct lubrication, and that in 98 per cent. of the manufacturing industries to-day, particularly in the United States and Canada, there has been very little attention paid to the tremendous losses which are incurred through improper use of lubricating oil.

Where the Trouble Starts

The trouble usually starts in the purchasing agent's office. In plants throughout the country the average number of barrels of lubricating oil consumed per factory is approximately 10, and to the purchasing agent, who is buying fairly large quantities of other materials, this seems to be an unimportant item. He is approached from time to time by salesmen representing different firms who sell lubricants, and as the salesman is often not a technically trained man, he has only at his command such knowledge as he has been able to acquire from years of experience, or has been given him by the firm he represents. No company or individual selling lubricants, who realizes the importance of correct lubrication, ever fails to train representatives and salesmen to offer high quality products. They also carefully train them to know the lubricant, which fits any specific case.

A salesman who has called several times on a purchasing agent without success, is very prone, in order that he may make a sale, to quote on low priced products, even if he is not sure they are the proper lubricants for the purpose for which they are purchased. This has been going on for so many years that purchasing agents, as a general rule, do their buying of lubricants principally on a price basis, and it is just as reasonable to suppose that people can buy a high class, high grade oil, at a low price as it is to think they can purchase a car of Cadillac quality for the price of a Ford. Quality carries with it a high price, and it takes no exhaustive or extensive arguments to prove this. All manufacturers have to do is to apply the principle to their own business.

To get back to the purchasing agent again, the oil salesman, and the number of years they have been going without careful attention being paid to the use of oil for lubricating purposes. About 90 per cent. of all purchasers of oil consider one thing, and that is the price. Now the mechanical superintendent, or superintendent of production, or whatever his title may be in the factory, is probably so busy trying to get produc-

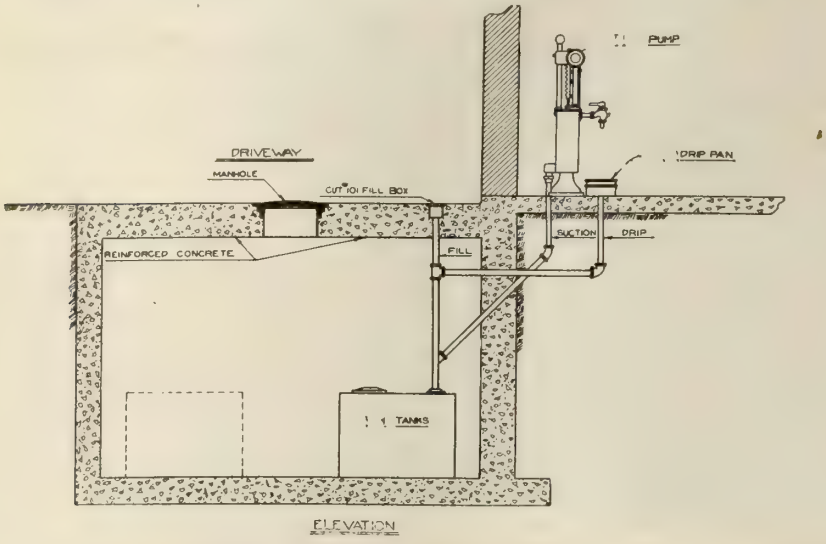
Withdrawing oil from pan of automatic screw machine

The matter contained in this article must not be used for any other purpose, as it has been written especially for Canadian Machinery. The author is sales manager and lubricating engineer for McColl Bros., Toronto, Ont.

tion up, or the cost down, that he has been an unconscious accomplice to the inefficient oil salesman and the purchasing agent. In other words he has been putting obstacles in the way of greater production, and lower costs, by taking and using the lubricants that the purchasing agent buys without making any exhaustive tests to see if they are the best for the purpose.

In 90 per cent. of the manufacturing industries and power houses in this country the methods of handling lubricating oils after they are received are very wasteful. They are usually kept in an exposed place where any one in the plant desiring oil can get it, and the oil is usually stored in either the original package with a common faucet screwed into the barrel, or in one of the old-fashioned tin tanks. The former method of storing, so common in this country, is very wasteful:

1st—On account of there being no way to salvage the drippings, or any oil that may be wasted on account of filling the container that is used to drain the oil from the barrel.



2nd—On account of the barrels becoming more or less dryed out and leaking.

3rd—There is great danger of some careless employee knocking up against the faucet and turning it on, and it is a common occurrence for complete barrels of oil to run away and be wasted because some person carelessly neglected to turn the faucet off, when he was through.

The latter method of storing oil in the old fashioned sheet iron tank, probably did away with the danger of loss by carelessness, as previously mentioned, but as these tanks are very loosely covered, the dust which is always in the air and which settles in most manufacturing plants, gets into the oil and causes it to become dirty. The bottom of the tank gets foul, and a great deal of oil from time to time is wasted, because it has to be thrown out, being unfit for use on account of the dirt that is in it. These tanks are not weather proof and as a great many oils draw dampness very rapidly from the atmosphere, they become impregnated with moisture, this materially affecting their efficiency as lubricants.

The First Step is to Prevent Waste

One of the first considerations of an economically operated plant, is the erection of an oil storage room in which there should be proper facilities for storing lubricants, and which should be kept under lock and key, the material being issued only on the superintendent's orders to the stockkeeper, so that the superintendent himself will have a record from the stockkeeper's report of which part of the factory, machine, machinery or department is using the most oil, or using an excessive amount.

Showing sectional view of oil storage

These storage facilities need not go into expensive equipment. The writer has in mind a very simple device which can be screwed into the top of a steel oil barrel, when the oil can be pumped out of the barrel as it is needed. These pumps do away entirely with leaking barrels or dust collecting oil tanks. Further, if there is anything wrong with the oil, the company supplying it will not be able to give the old hackneyed excuse that the oil was probably emptied into a dirty container or oil tank. By using this simple method of getting oil from barrels, it will never be exposed to the atmosphere until it is ready to be used. The steel barrel is merely rolled into the oil storage room, placed in position, and the pump screwed into the head bung of barrel.

There are many other more expensive oil handling devices, which of course, are more efficient and give a better check on the oil used, than the one heretofore mentioned, but in case a change in the class of oil should be decided upon by the management of the works, it becomes necessary to clean these tanks out. Also, if dirty oil should be put into them through mistake, and there is any of it left in them, it will not only spoil the oil you have on hand, but is allowing a loophole for the supplier to say that the oil was in good shape when it left his hands, and that he is sure the trouble was caused by the oil being put into a dirty tank.

The illustrations give an idea of different oil tanks commonly used in industrial plants, and we are indebted to the Canadian Tank and Pump Co., Toronto, for their use. Let us decide to come to the point where we are going to keep the oil as carefully guarded and issued as the most expensive material we use in manufacturing. Suppose we are going to be sure that all the oil we buy is issued for use on the machinery of our plant, and that we are going to hold the storekeeper accountable for it. If we do this, we have taken the first step in oil economy. We are, at the same time, going to give the operating superintendent of the plant an idea of how to intelligently figure out which machines in his plant consume the most oil, and which department is the most expensive to run from a lubricating standpoint.

The Selection of Lubricants

Careful estimates made by the most efficient engineers on the American continent, claim that practically 37 per cent. of the total horse power generated is overcome by frictional resistance. In other words, it takes 37 per cent. more horse power to do the work than is actually called for on account of friction. Friction reducing lubricants are essential to efficiently operated plants. Now, most any oil will lubricate, but the quantity which it takes to do the work indicates the amount of lubricating qualities in the oil. Lubrication is a study in itself, and a considerable mechanical knowledge is necessary, as well as a knowledge of lubricants and the conditions under which they work most efficiently.

The first step that should be taken by any prospective consumer of oil, should be to call into consultation a lubricating expert and get his recommendations as to which lubricants should be used on the different units in the plant, and how they should be applied.

The next step is to verify this specialist's recommendations. To do this, it is necessary to gather considerable detailed information. After the recommendations have been received, a quantity of the material, sufficient to make at least 30 days' run, should be purchased, very carefully stored as mentioned heretofore, and should be issued only on the presentation of an order signed by the proper authority.

The third step is to thoroughly cleanse all the lubricators in the plant, then clean the bearings. Next decide to use no oils or greases other than those recommended.

A very careful record should be kept of the amount of production that is turned out by the plant, the total number of hours the plant has run, and

(Continued on page 25.)

Anti-Slip Devices Save Time and Money

Prevention of Slip Vital to Safety—Positive Stops Prevent Sliding—Reducing Labor of Operator When Clamping Parts—Serration on Tool Face Adds to Efficiency

By FRED HORNER

AMONGST the numerous interesting featrues of machine tool operation that of slip prevention takes an important place. This essential is sought in certain portions of the machines, and in the tool-holding and work-holding appliances. The object in some cases is to prevent waste of time by having to re-set and re-tighten details of the mechanism, in other instances absolute prevention of slip is vital to safety. The results of untoward movement may mean a smash-up, or the work may be tooled to incorrect dimensions. These two points are more important in semi-automatic and automatic machines than in those where the operator is in constant attendance, or in machines doing general work, where the tools, etc., do not remain in fixed positions for long periods. Hence, an extra provision must be considered in many details of machine construction and tool-clamping devices, whereby a positive stop prevents the sliding of the part, this positive resistance acting in conjunction with the frictional mode of clamping usually adopted. Frequently the dead check to movement may be made to serve another useful function—that of fine adjustment—but occasionally the latter comes after the firm fixing and affords a small degree of correction for position. The precise method or arrangement depends on the type of machine under construction, and the facilities available for the introduction of the details. Some of the multiple tool-holders, for example, need different treatment to those of single-tool type, the construction of the stop plates or screws having to be made more compactly. The presence of other tools or sets of tools which range close together at certain intervals, likewise exercises a modifying influence on the check devices.

Conserving Energy of Operator

Another reason for applying anti-slip devices is to reduce the labor of the operator in clamping parts which are frequently tightened and loosened. By taking off the strain from a bolt or bolts by means of a positive stop, the wrench can be used with less exertion, and the bolts are not stressed severely in withstanding the pressure. Heavy cuts may be taken with perfect confidence, and no fear of sudden wrecking. One of the chief specimens of this class is the rack and pawl check for lathe tail stocks (Fig. 1), which is a valuable idea, since, otherwise, there is nothing to prevent the head from sliding endwise excepting the frictional hold of the bolts and plates.

Among auxiliary appliances the machine-vice is one of the most severely stressed, and frequently altered; consequently a favored device is that of notching out the face to engage a stop-strip which provides a positive thrust check to the moving jaw; or the base of the latter is made with a tongue (Fig. 2).

Another detail where end thrust is very great is the tool-bar employed in slotting machines, and in vertical planers. The method followed is either to bolt a positive stop-block on the ram to touch the tool end, Fig. 3, or to machine serrations across the back of tool-burr, and provide corresponding serrations on the face of the tool-slide, the bar being adjusted to the desired vertical relative setting and then clamped. The serration of tool-bars in this fashion is a different thing from dealing with the tools themselves, which are fashioned from plain steel, and do not as a rule pay to cut notchings on. Therefore if anti-slip has to be arranged for, it must either proceed from some feature incorporated in the structure of the holder, or an auxiliary screw needs to be located to come in the path of the tool, and block it.

Thrust On Slotter Tool Bar Preventing Slippage of Disc Tools

Disc or circular tools, such as for threading or forming, are not so easy to deal with as the rectangular tools, and the practice in regard to them is either to enhance the frictional grip enormously, or to cut face serrations, or make a hub with flats, so that a special washer or a rocking arm can be utilised to gain a positive grip. A mode of supplementing the frictional grip, while still allowing the heading disc to be turned into fresh positions after repeated sharpenings, is illustrated in the lathe tool in Fig. 4. The disc is not pulled against a plain flat face, but is built with a coned hub, to fit a corresponding taper in the bar; this supplies a frictional clutch of immense holding capacity, and extra to this there is a taper bush fitting inside the bore, the setting up of the screw bringing these two grips into action. Another principle, which is applicable to any of the circular forming tools employed in the automatic, is represented in the Brown & Sharpe holder seen in Fig. 5, where a hook-bolt, A, drawn against the tool flank gives what is in effect a large washer pressure over the side.

Serrations on the tool face add to work of manufacture but give a powerful hold positive against slip. The method of locking is preferably with a toothed washer forged with an extension arm, the end of which is raised or lowered by nuts on a screw. A similar idea serves for adjusting the holders for rectangular-blade tools, which latter are clamped in the rocking holder after the style of Fig. 6. By milling a hexagon or octagon upon the hub of a tool an alternative source of non-slip hold is afforded, a swinging arm being placed

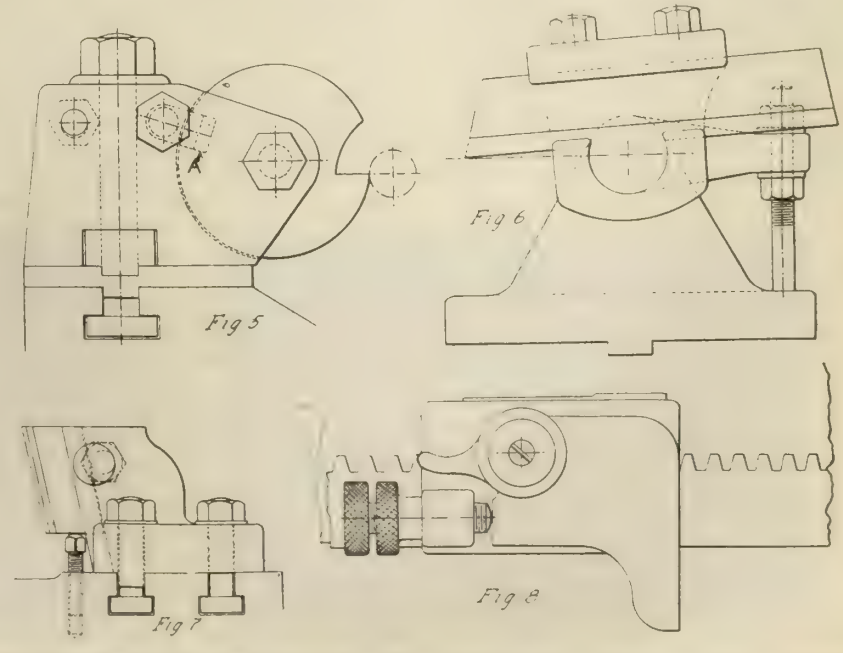


Fig. 5.—Locking cutter with hook bolt. Fig. 6.—Rocking type of locking device. Fig. 7.—Taking care of vertical thrust. Fig. 8.—Spring latch locking device.

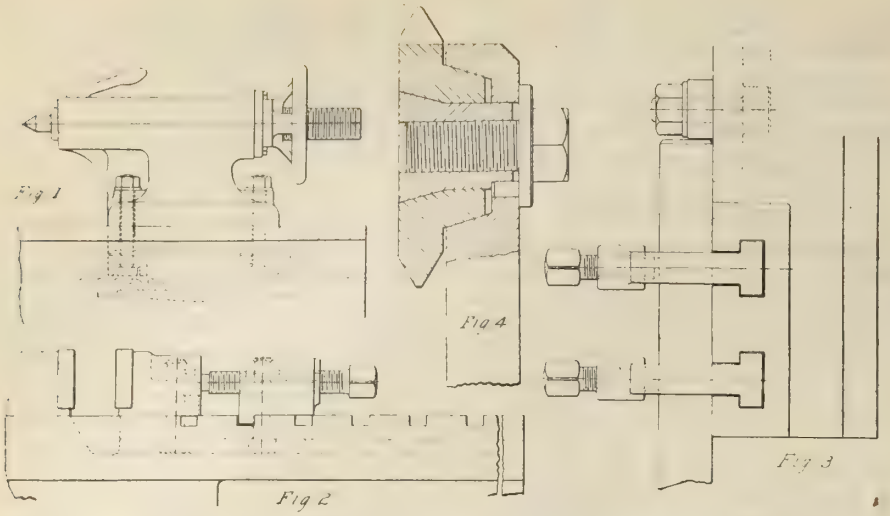

Fig. 1.—Rack and pawl locking device. Fig. 2.—Tongue and groove non-slip. Fig. 3.—Lock fitted with serrations. Fig. 4.—Double cone friction lock.

over the hub to control it by the slewing of the outer end of the arm.

The majority of the straight tools which are held in boxes and set to cut certain sizes are either secured with ample set-screws, often aided by serrated seatings or clamp-plates, or they are set up and afterwards sustained by back screws. The latter are the more positive way, and besides in some instances may serve as stops for convenience in replacing the cutters after touching up their edges. This applies also to many kinds of boring bars and heads fitted with backing screws for the cutters.

Anti-Slip Thrust Screw

Flat forming tools, whether presented in the ordinary or in the inverted position, are best sustained by a thrust-screw (see Fig. 7 for example), so that no amount of pressure from the work can cause displacement. A similar tool, the thread chaser of form type, happens to be checked in a different fashion; the adjustment here is effected by a small screw at one corner, partly fitting the chaser and partly the holder, hence end slip is impossible so long as the screw is in place.

Another feature which affects the operation of some machines is automatic tightening when an element tends to slip. The degree of tightness consequently varies with the amount of cutting pressure. The tightening is brought about by wedge cam, or eccentric action, or by screw and cone, etc. Many of the modern drill chucks operate on such a principle, so also do some of the heavy face-plate driving dogs utilised for wheel turning, and shaft dogs for grinding.

Reversing and feed dogs for grinding machines afford a further example of anti-slip fitting. To prevent sliding of dogs upon the bar, and possibly causing the fracture of an expensive grinding wheel as well as other damage, the best device is that of a rack on the bar. Fig. 8, spring latches locking the dogs thereto. The final adjustment is performed by the screw and lock nut. This practice makes for convenience in operation, since a dog can be raised to let the table run past the reversing locations, and the rack teeth ensure accurate replacement of the dog subsequently.

Side Slippage of Tools

Anti-slip devices considered in regard to the holding of pieces for machining, chiefly assume the form of dead stops. These, which are extensively utilised on such work as planing, to resist the tool thrust, are represented in another manner in innumerable jigs and fixtures, where solid faces, or ledges, and locating screws prevent any chance of movement. The risk of slip in planing is to be feared so often that the stop pegs, or bolted brackets on the table are in frequent request; what is more troublesome, however, is the chance of side skidding, which causes the piece to slew round and probably induce serious disatser to work or tools. The end stops alone do not always prevent this, particularly when cuts occur at extreme edges, and side stops have to be included. It is better to consider these seriously at first, and spend a little extra time in setting up than to incur skidding soon after the tooling has commenced.

Another condition where slip has to be guarded against is in cutting gears, including ba ches clamped together. Friction of the binding washers, or of the face-plate when such is used may or may not be a sufficient surety against slip after cutting has begun. But it is safer under slogging cuts to gain a drive with a pin against an arm or opening, or use a clamp which will always keep the blanks in the original position. When cutting spirals, especially, the torsional stress is very great (particularly in planing with multiple-toothed shaper tools) and the blanks should be keyed on to the arbor, or held very tightly, while the latter is keyed into the spindle.

Why Men Succeed

"SUPPOSE a young man is working in an office or a shop on small pay, and wishes to gain an increase so that he can marry, what would you advise him to do?" was the question put to Henry Ford.

"The fact that a young man has been on the pay roll for a long time, or wishes to marry, is not enough to justify an increase. He must get results of some kind. Many young fellows, especially those employed in offices, fall into a routine way of doing their work that eventually makes it become like a treadmill. They do not get a broad view of the entire business. Sometimes that is the fault of the employer, but that does not excuse the young man."

"Those who command attention are the ones who are actually pushing the boss. To be specific, get books and read up on the industry in which you are employed. If you are working in a bank, study banking. If you are selling clothes or dry goods, study the business from every angle. Get ready for a promotion before there is any actual vacancy. Be prepared for your opportunity when it comes. It pays to be ahead of your immediate job, and to do more than that for which you are paid. A mere clock-watcher never gets anywhere. Forget the clock and become absorbed in your job. Learn to love it. If you follow these suggestions you will not have to ask for an increase in most instances."

"Should a man talk over his business affairs with his wife?"

"Certainly. Isn't she his partner? And besides, she may have more sense about some matters than her husband. Two heads are always better than one."

"Do you think there has been an increase in pleasure-seeking among the young people? In other words, are they going pleasure-crazy?"

"Oh, no," he replied, shaking his head. "That is merely a passing fever. Did you ever stop to think why young people are so eager to have a good time?" he interjected abruptly. "It is because they crave experience and self-expression. Life is new and strange and they are stirred by the spirit of adventure. After that has been satisfied to some degree, they settle down and lead healthy, normal lives."

WATCH FOR THIS

It is one thing to own precision instruments, and another to know how to use them with maximum efficiency. Whether you actually own such instruments or not, it will pay you to read next week's Canadian Machinery, in which you will find a detailed article on the subject of the "Proper method of using precision instruments."

Methods of Handling and Heat-Treating Springs

Principles Governing Uniform Heating And Cooling—Cost Element Dependent on Many Things—Type and Arrangement of Equipment—Stationary and Continuous Furnaces—Utilizing Heat In Waste Gases

IN THE heat-treatment of springs, probably more variation occurs in methods of heating and handling than in the heat-treatment of any other standard fabricated steel product. This variation is due to the necessity of producing springs of different physical characteristics and in irregular quantities to meet a diversified demand.

The variety in size and shape of vehicular springs, with the still greater variety in the nature of springs for special purposes, and the divergent manufacturing conditions, make no two cases exactly alike. This calls for different methods of heating and handling in the practical application of the fundamental principles of heating and cooling upon which the heat-treatment of good springs is based.

Vehicular springs are now required in thousands where comparatively few were previously needed. Then, too, the springs on modern motor vehicles are subjected to much harder service than were those on the horse-drawn vehicles of the past. But even to-day the methods of heat-treating springs are occasionally below the relative standard of quality set by the old-time blacksmith, who with his skill overcame the disadvantages of inferior material and equipment and produced a limited number of comparatively good springs with a coal fire. It is fortunate, however, that high-grade steel and improved forming and heating equipment are now available, so that with correct methods of heating and handling, better springs may be obtained at less cost.

Making Special Springs

In the manufacture of special springs, particularly in the jobbing shop, the variety in the shape, quantity and methods of heat-treatment are such that it is difficult to approach even the limited degree of standardization in method of heat-treatment that is possible with vehicular springs. In either case the principles governing uniform heating and cooling cannot be disregarded without a sacrifice in quality, although there is great latitude in the design of equipment which will provide an efficient method of handling the springs.

In the up-to-date spring shop great care is taken in the process of manufacture to insure high quality product. The element of cost is dependent not upon quantity production alone, but is also greatly influenced by methods of heating and handling, design and arrangement of equipment, and efficiency of the operatives. The proper co-ordination of all these essential factors generally results in improved quality, decreased cost and increased business.

To heat correctly is the first consideration in the manufacture of quality product. The process of heat-treatment, method of heat application and influence of the "human element" predominate.

To heat economically it is necessary to consider the influence of the type, size, number and arrangement of heating, cooling and handling units upon the items of output, labor, fuel, floor space, investment, and such other items as may properly be included in the actual cost of production.

The fundamental factors governing the uniformity of heating and cooling, which are based upon the elements of temperature and time, and the mass and surface of the individual piece exposed to the heating or cooling medium, cannot be ignored without a sacrifice in quality and ultimately in cost of the finished product.

The relation of type and arrangement of furnace equipment to the cost of product is not sufficiently appreciated. This is primarily due to disregard of the fact that the cost of production is very largely influenced by the nature of equipment and method of heating and handling, not by the price of fuel alone.

Furnaces are too generally selected merely with regard to the nature of fuel or heating energy for generating the heat, or with reference to the method of handling the material, and with disregard of the method of applying heat to the individual spring. Although efficient methods of handling are necessary from the standpoint of production, it is just as important to provide for proper application of the heat to insure good quality. Poor heating conditions, resulting in uneven coloring of the springs or dark spots in the heating zone, are generally disclosed in service.

Uniformity of Heat

Proper consideration is not usually given to the difference between indication of uniform temperature at some point in the furnace chamber and the uniformity with which the heat is applied to the individual piece. Indication of temperature control may be accepted as evidence but certainly not as proof, of control of heated product; for, unless there is proper method of heat application and loading, and regular input and output of material, keeping the chamber substantially and continually filled to capacity, it is not likely that a uniformly heated product will be produced even though there is a uniform delivery of heat to the chamber.

The great variety of plant conditions and production requirements make it difficult to develop any one process of

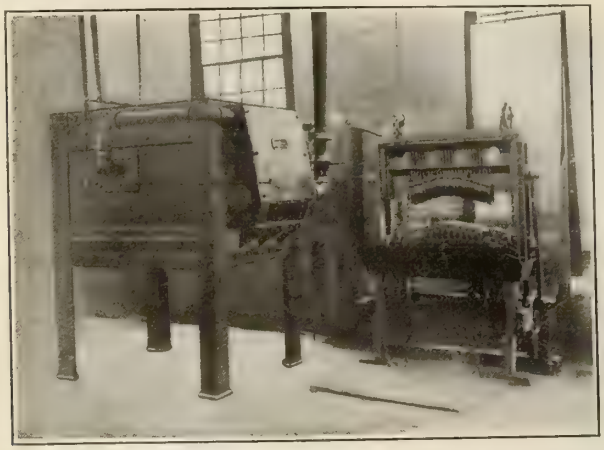
heat-treatment, method of production, type of machine or furnace that may be considered a standard for the production of high-grade springs at low cost. Even with an established process and type of machine, the variety of plant conditions, such as nature, quantity and flow of material, cycle of operation, floor space, available fuels, etc., affecting the type, size, number and layout of furnaces, invariably make it necessary to adapt the furnace equipment to the plant conditions.

Formerly, one small chamber heated enough stock to keep one fitter busy. The fitting, hardening and drawing operations were frequently performed in the same furnace and at practically the same temperature, the judgment of the fitter being depended upon to determine both the temperature and the period of time required.

The demand for better quality and decreased cost indicated the inherent weakness of such methods. The advent of machines to meet the pressing demand for quantity production has led to the development of different types of furnaces to meet the equally pressing demand for better methods of heating, cooling and handling.

There is marked contrast between the hand-fitting operation, Fig. 1, the simple types of fitting and shaping machines, Figs. 3 and 4, and the more elaborate forming and quenching devices, Figs. 5 and 10, for shaping the spring. This contrast, however, is no greater than that between the old-fashioned single-chamber furnace with its one-heat method of operation, dependent almost entirely upon the skill of the operator, and the improved types of stationary multi-chamber furnaces, Fig. 2, and different types of modern automatic furnaces. Such modern furnaces not only contribute to an improvement in quality through better methods of heat application, but also materially reduce the cost of production through the economies effected in labor, fuel, floor space, equipment, and number of operatives per unit of production.

Three-Heat Method



In the hand-forming of vehicular springs the three-heat method is preferred. The leaves are heated for shaping, again for hardening and finally for drawing. In such hand-fitting, and wtih some machine-forming operations, stationary furnaces in single or multi-chamber form may be employed. Double-chamber furnaces, Fig. 1, with separate chambers for hardening and drawing, and a separate furnace for fitting, may be made necessary by the shop conditions.

Three or six-chamber furnaces, Fig. 2, arranged for one or two screws, as preferred, with separate chambers for fitting, hardening and drawing represent the modern practice for hand-forming with stationary furnaces and are generally preferred for the advantages they afford in concentration of operation, saving in floor space, efficient methods of handling, etc. The size, number and arrangement of chambers in such stationary furnaces are dependent entirely upon the shop conditions and manufacturing requirements.

Continuous furnaces of automatic or semi-automatic type for machine forming are used in a variety of design, with different methods of generating and applying heat and methods of handling the springs. When the plant conditions permit, the use of such furnaces generally leads to improved quality of product resulting from uniform time of exposure and rate of heating, also a lower production cost through more efficient methods of handling the product and utilizing the heat.

The continuous furnace has its limitations. It performs to best advantage when the size, shape and composition of the stock are fairly uniform; and when the supply is regular and sufficient to permit of substantially continuous operation at full capacity. Its field of usefulness is narrowed when the supply of stock is irregular and the operation intermittent; when there is a distinct variation in the size, shape or quantity of the stock to be heated, or by other conditions that do not make the operation as a whole strictly continuous.

The continuous conveyor type, Figs.

Fig. 5.—Showing forming machines and quenching tanks at discharge end of multi-chamber furnaces.

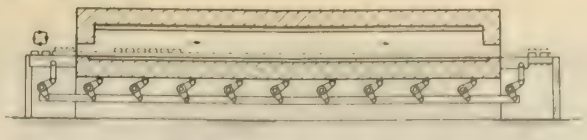

Fig. 9.—Section of intermittent conveyor type furnace.

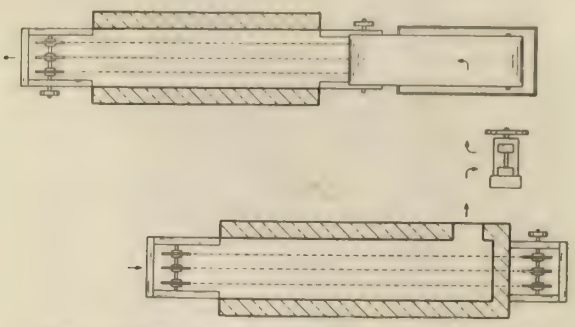

Fig. 11.—Floor plan of hardening and tempering furnace shown in Fig. 10.

6 and 7, in which the material rests upon and is continually carried by an endless conveyor, may be employed in a variety of forms for conducting the various heating operations separately or in sequence. Fig. 8 illustrates furnaces for special springs, with provision to decrease time of exposure in cooling by discharging from within the chamber and automatically conveying the springs to the drawing furnace.

The intermittent conveyor type, Fig. 9, intermittently conveys the stock through the chamber floor bars, between which the conveying mechanism operates, in a series of steps or stages.

The rotary table type is provided with a metallic hearth entirely within the heating chamber, Fig. 12, or with a refractory hearth, Fig. 13, of which only the carrying surface is exposed to the heat. Modifications of either type, with regard to method of charging and discharging material, are made to suit individual requirements. This furnace is, by reason of the shape of the hearth, limited to conditions where the length and shape of the spring do not seriously affect the carrying capacity of the hearth.

The pusher type, Fig. 14, is another form of semi-automatic furnace which is frequently made necessary by provision to carry the springs on trays, or when the size and shape of the springs and the process of heat-treatment warrant its use.

Drawing Coloring or Drying

The car type furnace, Fig. 15, may be considered for drawing, coloring, or drying comparatively large batches of springs. It is built in the single-chamber type, as shown, or double- chamber type, in which the car is alternately charged and withdrawn. It is also built in either of these forms with openings at both ends, so that one carload may be drawn into the chamber as another is discharged.

Endless combinations of such furnaces as illustrated by Figs. 8 and 11 may be effected to suit individual requirements without eliminating the continuous feature of heating and handling. A continuous furnace may be arranged singly or in series to serve one machine. One furnace may be arranged to serve two machines, with provision to automatically remove the springs from the quenching bath, after hardening, to the drawing furnace.

Frequently it is necessary to arrange combinations of continuous and stationary furnaces by reason of some manufacturing requirement which prohibits the strictly automatic method of production but nevertheless permits of practically continuous heating and handling in the fitting, hardening and drawing operations.

The design of furnace and detail arrangement of conveyors, working openings, etc., are affected by the nature of the heat-treating process, the size, shape and quantity of the stock, methods of charging and discharging, and the floor space. These factors determine the design, number and layout of furnaces in the shop.

Special forms of springs in large quantities are heated to advantage in the furnace illustrated by Fig. 16, the conveyor being adapted to the physical characteristics of the individual piece.

Large quantities of rods for the manufacture of agricultural springs are continuously heated for forming, hardening or drawing in the continuous furnace illustrated by Fig. 17.

Drawing operations may be performed in oil baths when the temperatures are comparatively low; or when the temperatures are higher, in baths of salts or metals with low melting point. Stationary types of such furnaces are provided with a single pot, Fig. 18, or with double pot, Fig. 19.

Combinations of bath methods of heating with continuous methods of handling are illustrated by Figs. 20

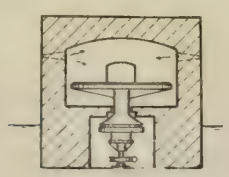

Fig. 12.—Section of rotary table furnace.

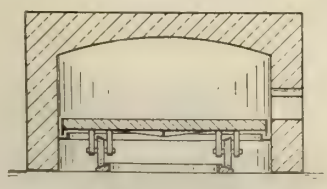

Fig. 13.—Section of refractory hearth type rotary table furnace.

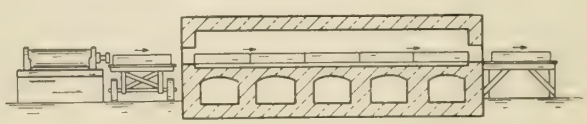

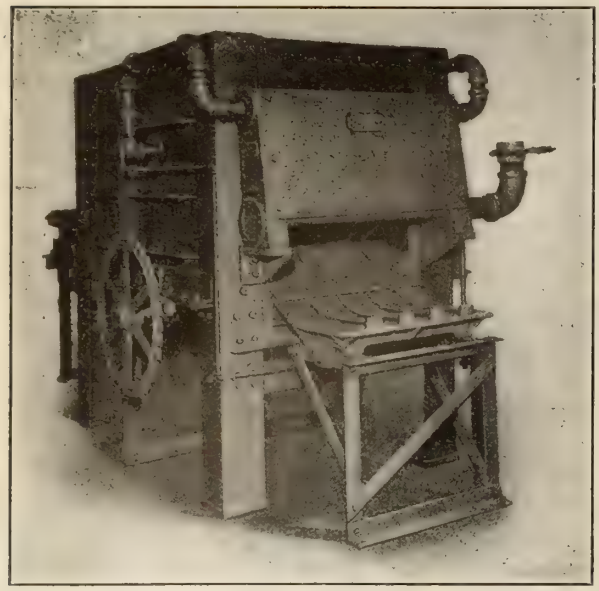

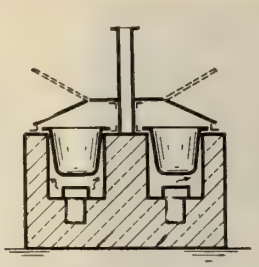

Fig. 14.—Furnace fitted with mechanical pusher.

Fig. 10.—General view of furnace room with forming machine and quenching tank in foreground.

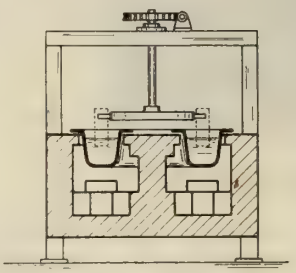

Fig. 17.—Continuous heat treating furnace for rod stock. Fig. 19.—Twin pot tempering furnace. Fig. 20.—Continuous type of bath tempering furnace.

and 21. There are a great variety of furnace designs embodying these methods of heating and handling, the selection depending upon the nature of the product and the manufacturing requirements. With such furnaces the advantages of the bath method of heating and a continuous method of handling make possible a result, in quality and quantity of product, that cannot be produced with the ordinary type of pot furnace.

With an equally efficient method of applying the heating or cooling medium to the entire surface of each piece, satisfactory results in drawing are secured, without the use of a bath, in furnaces having a uniform heating chamber atmosphere.

For tapering, nibbing or miscellaneous end-heating operations, the type of furnace illustrated by Fig. 22 has proven very satisfactory in practice. A novel feature of this furnace is a special type of economizer shield, Fig. 23, placed over the working opening to protect the fitter from the heat and utilize the heat in the waste gases, which are deflected upward to preheat the air and fuel for combustion. This construction reduces the fuel consumption, promotes combustion and permits location of the furnace close to the machine, Fig. 22, thus enabling the fitter to work more efficiently and in greater comfort.

Arrangement and Operation

The economies which may be brought about by intelligent selection, arrangement and operation of equipment properly adapted to individual plant conditions, exert no small influence on the items of labor, fuel, output, floor space, investment and other items included in the actual cost of production.

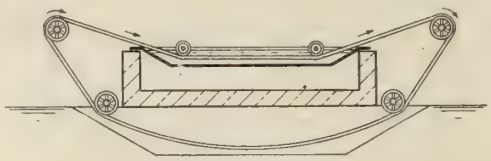

Fig. 20.—Continuous type of bath tempering furnace.

Fuel or electricity may be used for generating heat in such heat-treating operations. The form of fuel or electricity to use depends upon the nature of the heating operation, manufacturing requirements, plant conditions, prices of available forms of fuel or electricity, and the type of furnace most suited to all of these factors.

The form of the heating energy must be considered with the form of the furnace, not only with reference to the manner in which the heat is released or controlled, but to the manner in which the heat is applied to the individual piece, and the method of loading and handling the material to be heated.

A given form of fuel or electricity and method of heating and handling may make possible a design of furnace which will accomplish a result, in quality and cost of product, not apparent from consideration of the form or price of the fuel or electricity alone.

The physical difference between anthracite and bituminous coal, in solid or powdered form, coke, fuel oil and hot or clean gases, must be considered along with the difference in composition of the gases resulting from the combustion of such fuels, and the possibility of overcoming an apparent disadvantage in the physical or chemical form of low-priced fuels with suitable furnaces.

Likewise, electricity must be considered with reference to the difference between the arc, induction and resistance methods of generating heat; the composition of different forms of resistors or these forms of electricity, and the heat-electrodes, which may affect the composition of the heating atmosphere; the position of the heating elements in relation to the material to be heated; the heating and handling requirements of the different types of furnaces adapted to individual plant.

Frequently the apparent disadvantages in physical form of low-prices bituminous coal are offset by a proper method of heating and handling material in suitable furnaces. The apparent advantages of the arc, induction or resistance forms of electricity are frequently offset by improper furnace design, just as apparent disadvantages in

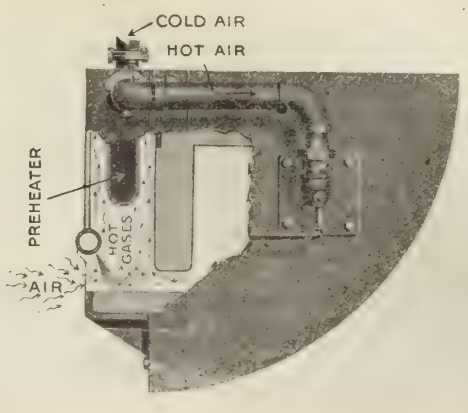

Fig. 23.—Showing deflection of hot gases and preheating of air for combustion.

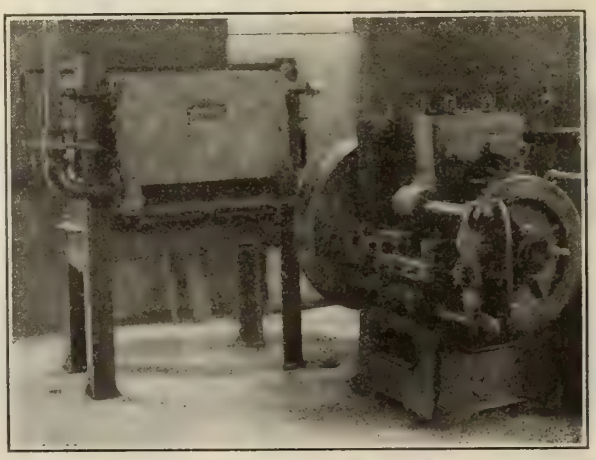

Fig. 22.—Furnace for heating ends of stock, with forging machine adjoining.

prices are frequently overcome by suitable designs of furnaces which decrease the amount of energy required and accomplish a result, in quality and cost of product, that would not be otherwise possible. An apparent failure with a given form of energy in one instance and an apparent success with it in another, must be considered with the variable element in the design of furnaces that accounts for the difference in result.

No one form of fuel or electricity or furnace is suitable for all conditions. The selection of either is largely a matter of compromise in reconciling requirements of quality with others related to methods, plant conditions and cost of production.

The quality of the heated product reflects the uniformity with which the heat is applied to the surface of the individual piece and the heating atmosphere in which it is exposed. The nature and price of a given form of fuel or electricity, and the method of controlling the quantity supplied to a furnace, must be considered with other equally essential factors that control the uniformity and cost of the product itself.

The cost of production is governed by many factors affecting the items of labor, fuel or electricity, output, floor space, investment, and other items entering into the actual manufacturing cost. It is also largely influenced by the intangible values in quality of product resulting from proper methods of applying heat to the product.

The price of fuel or electricity must be considered with the amount consumed and the nature and cost of the ultimate result made possible by the intelligent use of the right form of energy in the right form of furnace. The problem is one of selecting that combination of furnace and fuel or electricity which, wtih proper methods of applying and utilizing the heat and handling the material, will produce the best quality product at the lowest cost, all things considered.

REDUCING EXPENSE BY CAREFUL OIL SUPERVISION

(Continued from page 18)

all information that will give to the superintendent the actual amount of work completed, so that he can compare it with the amount of oil used. Against this production and the amount of oil consumed, should be figured the energy consumed in driving the plant, that is the amount of fuel burnt, or the current used, etc., etc.

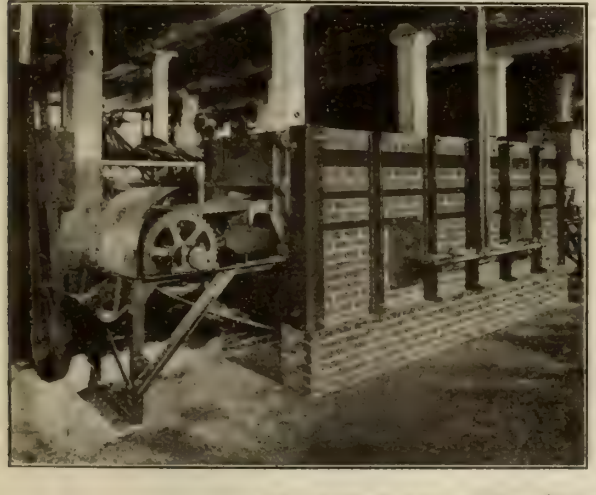
The same procedure should be followed at least thirty days previous to the time that you started to use the recommended lubricants, that is before the time you start in to take advantage of your lubricating engineer's recommendation.

By comparing the first 30 days—that is the time you were running on the old lubricants and the time you were running on the new lubricants—you would be able to determine the amount of power used, the cost of same, the amount of material produced, and the amount of oil per unit consumed. By comparing these figures, you will easily determine the value of the new lubricants you are using and you will be surprised that, although in many cases, the oil or lubricant has cost you 100 per cent. more, the amount of fuel or power you have saved, plus the saving on oil, plus the increased production will be tremendous. The oil saving may not be due to the fact that it took less oil alone, but will probably be principally due to the careful way it was issued and the care that was taken in applying it. The saving may not be due entirely to the oil, the increased production may not be due entirely to the oil, but it may be due to the application of it.

Mistakes Commonly Made

From time to time engineers have attempted to offer manufacturers and consumers of lubricants, tables of specifications, which some purchasing agents and mechanical superintendents have attempted to follow. This is perhaps the greatest mistake that has ever been made. There are so many local conditions, such as atmospheric temperature, rev. per minute, methods of application, length of run, method of storing, system of using oil, and these specifications are not always applicable to the individual case in question.

A common mistake that we frequently come in contact with is the effort of the manufacturer or general manager to keep their processes, systems, etc., a secret. Unless you can take the lubricating engineer or lubricating salesman into your confidence and tell him what you are doing, the conditions the factory is being operated under, etc., you cannot expect him to be able to make very intelligent recommendations. It is just as foolish to suppose that he can go to the purchasing agent, have him ask for a price on engine oil, stop there, and expect the salesman to quote on the correct oil to be used. A physician could not intelligently prescribe medicine for a sick person, if he were not allowed to get the person's temperature and generally examine his condition. There is no question too minute, or nothing that is of no importance in connection with lubrication.



Another mistake we commonly come in contact with is the purchasing agent, mechanical superintendent, or salesman, who has a half knowledge of his subject and thinks that he knows all there is to know about it. We cannot all be specialists. The purchasing agent is not expected to know the technique of lubrication, neither is the mechanical superintendent, and it is hardly fair to expect that an oil salesman will know it all.

What Should be Done

At least once every two years, purchasers of lubricants should keep a very careful record for at least thirty days on the number of pounds or gallons of lubricants consumed; the amount of fuel used to generate power; the amount of hours running, etc.; the time lost for repairs, hot boxes, etc.

Purchasers should also figure the lubricating cost per unit of production, the fuel or power consumed per unit of production, and the number of hours shut down for repairs, etc. They should then call in a lubricating expert, give him all the data they have on hand and free access to the factory for as long as he wishes. After he makes his recommendations, they should be carried out carefully, and the same data as above mentioned kept and a comparison made between the two sets of figures.

First class lubricating companies are always willing to furnish to the oil consuming trade, the best advice that can be had, and most first class companies maintain an efficient corps of lubricating engineers who work in conjunction with their regular salesmen on cases where this is necessary. There is usually no charge for this man's services to the consumer and in 99 times out of 100 the benefit the consumer receives from such advice, is very far reaching.

Designing Machine Screws and Bolts

Fundamental Principles—Various Thread Shapes and Their Respective Uses—Screw Thread as a Power Medium—Thrust Factor Depends on Shape—Safety of Bolts—Pipe Threads

By L. T. RUTLEDGE

SINCE we have considered the designing of a triple riveted butt joint in the Feb. 9 issue, we will next take up the threaded, or screw type of fastening.

A screw fastening, intended for holding two or more parts together, is a cylindrical shaped piece fitted with a thread. The fastening may be either permanent or temporary but, as a general rule, the fundamental feature of bolts and screws is, that parts connected with them may be easily disconnected when required. In this latter particular it is quite different from a riveted fastening.

The study of threaded fastenings will be introduced in this discussion by considering the type of threads in general use, and the form of screw fastening as a complete fixture.

Type or Form of Thread

The various forms of thread in common use are the United States standard or Seller's thread, the V-thread, Whitworth, square, trapezoidal, Acme, and the standard Brigg's pipe thread. Fig. 29 shows the various forms of threads.

Though the more general function of threaded fixtures is to serve as fastenings, nevertheless they are used for the purpose of transmitting power. A lead screw on a lathe moves the carriage along the bed. A screw-jack is used to raise heavy loads and sustain them. It will be apparent that the efficiency of the screw has to be given some attention, when transmission of power is effected. In this discussion, the latter application of threaded fixtures will be considered along with the more general application.

The two common forms of thread in use in Canada and the States are the "V" and United States standard. Both forms are strong, may be produced quite easily, and, due to their low efficiency, they are well adapted as a screw fastening. A low efficiency indicates a high friction and it is apparent that the higher the friction between the screw and the metal it is threaded into, the more serviceable the fastening. The two forms of thread resemble one another, the angle between the sides being, as shown, 60 degrees. The U. S. thread differs from the older V-form in the respect that the sharp point is absent. A flat equal to the pitch divided by eight, or $\frac{P}{8}$, is left on the top, and also at the root as shown in 29(a).

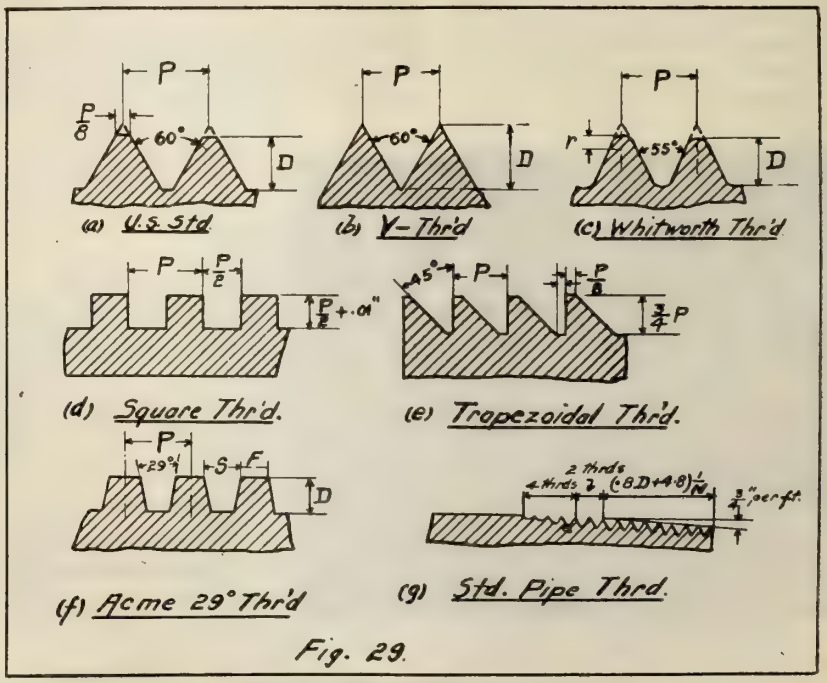
The depth of the V thread equals P x 0.86603, whereas the depth of the U. S. thread is p x 0.64952. The V and U. S. screws have the same number of threads for each standard size except in one instance, namely, for the ½ inch size. A ½-inch U. S. cap screw has 13 threads per inch, whereas a ½-inch V-thread cap screw has 12 threads per inch.

Whitworth Thread

The Whitworth thread is the principal one of the English standard threads, used on bolts, screws, and machine parts. It differs from the Seller's thread in so far as the angle is 55 degrees instead of 60 degrees, and in addition has the crest of the thread, and the space at the root, rounded by a circular curve instead of being flat. The radius of the rounded part is p x 0.1373. The depth of the thread is p x 0.64033. The number of threads per inch for the various standard sizes of bolts and screws corresponds exactly with those of the V-thread standard.

The greater percentage of the ammunition furnished by Canada under English specifications during the period of the late war was fitted with Whitworth threads. For some considerable time our mechanics experienced some little difficulty in cutting accurate Whitworth threads. The main difficulty seemed to be due to maintaining a uniform pitch throughout the thread length. The variations in the profile affected the pitch line. However, as soon as accurate thread gauges were available the trouble disappeared.

Square Thread



The square thread, as well as the trapezoidal and Acme, is adapted for the transmission of power. The square thread has great strength and also high efficiency. This latter property is essential on account of the use to which it is put. A very important advantage is that the thrust is very nearly parallel to the axis of the screw and therefore has no bursting strain on the nut.

It has a couple of serious disadvantages, viz, it is difficult to take up any wear which may occur, and the cost of manufacture is much greater. The proportions of square threads have never been standardized as in the case of the preceding types. However, the proportion given in Fig. 29 (d) is a common one.

Trapezoidal Thread

The trapezoidal or buttress thread, shown in Fig. 29 (e), is occasionally used for the transmission of power in one direction only. In cases where there is little work to be done during a reversed motion, as in some presses, and when used on the breech blocks of large guns, the effect of the oblique thrust is negligible and this is often the best form of thread for the purpose.

Thus this type of thread to a certain extent combines the important feature of the square thread already explained, with the strength of the V-thread.

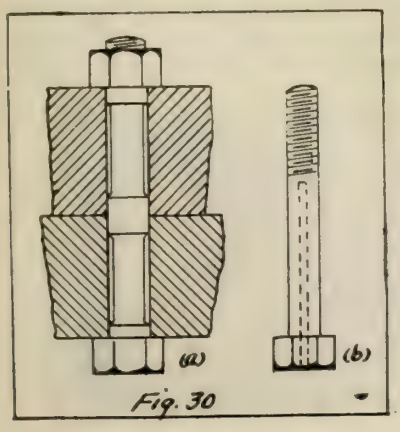
Showing Various Forms of Screw Threads.

The author is Professor of Mechanical Engineering at Queen's University, Kingston, Ont., and should any reader wish help in any problem on mechanical matters, write us, and we will see that Mr. Rutledge supplies you with the desired information.

The acme thread, as illustrated in Fig. 29 (f) is an adaptation of the most commonly used style of worm thread, and is intended to take the place of the square thread. It is a little shallower than the worm thread but generally the same depth as the square thread and much stronger than the latter. The wear can readily be compensated for by an adjustment of a split nut used in conjunction with it, as is done in the case of the lead screw of a lathe. Acme threads can be manufactured in quantities at a low cost.

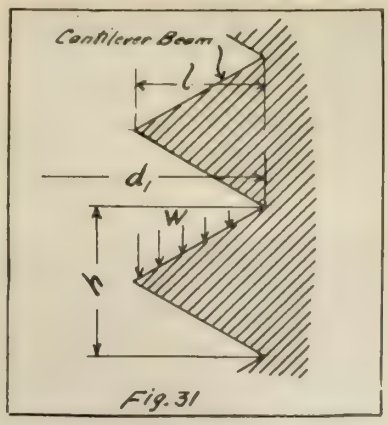
The values of the dimensions as given in the illustration in terms of the pitch are as follows:—

$$P = \text{linear pitch} = \frac{1}{\text{No. of threads per inch}}$$



$D = 0.5P + .01$ in.
$F = 0.3707P$
$W = 0.3707P - .0052$
$S = 0.0293P$
$B = 0.6293P + .0052$

Many of the above values are determined from a trigonometric function of 29 deg.



In Fig. 29 (g) is shown a section of a standard gas pipe thread. This type must be considered only as a special type of fastening and not for the same class of service as those discussed previously. The illustration shows the total length of thread divided into three parts. The first part at the end of the pipe, shows a perfect thread, top and bottom, over a tapered length of $(0.8D + 4.8)\frac{1}{n}$—in which D is the outside diameter, and n the pitch.

The middle part has two threads which are full at the root, but imperfect at the top, and not on the taper. The third division has four imperfect threads, flat on the top and bottom. The taper of the first section is ¾ inch per foot.

It should be borne in mind that commercial sizes of iron pipe are given by the size of the bore. Thus, a ½ inch iron pipe has a hole through it approximately ½ inch in diameter, which is the nominal inside diameter. The actual inside diameter as given in Briggs' table is 0.623 in. The actual outside diameter is 0.840 in., the number of threads per inch 14, diameter at end of pipe due to the taper 0.815 in., root diameter of thread at middle section 0.701 in., depth of thread .057 in., length of perfect threads 0.39 in., number of perfect threads 5.46.

Reducing Area of Bolt Body

V Thread Diagram

Forms of Screw Fastenings

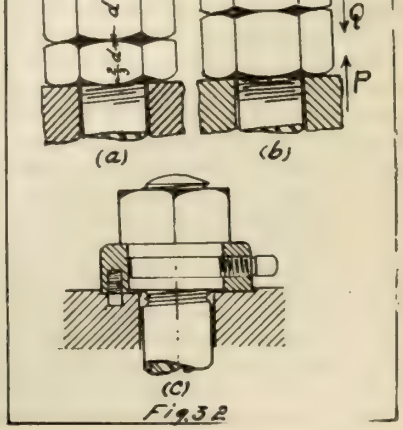
The following important commercial forms of screw fastenings are met with:—(a) bolts cap screws, (c) machine screws, (b) set screws, (e) studs (f) lag screws, (g) stay bolts. We will discuss these briefly and in the order given.

Bolts:—A bolt is similar to a rivet in the particular that it is a round bar with one end upset to form a head but it differs to the extent that the other end is fitted with a thread on which a nut is threaded for holding purposes. Bolts are well adjusted for holding two parts together rigidly and at the same time permit of the parts being dis-assembled by simply removing the nut. The holding is accomplished by the friction of the thread on the nut with the thread on the shank of the bolt and the friction of the nut on the bearing surface of the machine part. The under side of the head of the bolt takes bearing as well as the nut. Bolts are divided into the following common classes, namely, machine, carriage, coupling, automobile, and stove bolts.

Screws:—Screws, unlike bolts, do not require a nut but are threaded directly into the pieces to be fastened. Where two members are to be held together, one of them is fitted with a clearance hole for the screw, and the other is fitted with a tapped hole to receive the screw. Cap screws, and machine screws hold by the pressure exerted by the head of the screw, whereas set screws hold by the pressure of the point.

Studs:—A stud is a bolt in which the head is replaced by a thread so that the stud has a thread on each end, there being a section at the middle with no thread. The stud passes through one of the parts to be connected such as a cylinder head cap and is screwed into the cylinder end. A nut, screwed on the outer end, serves to hold the cap on. Thus the stud remains in position when the parts are disconnected.

Lag screws, also called coach or wood screws, are in a class by themselves. Ordinary lag screws have threads made by the die or rolling process, which gives a good enough thread for the purpose to which the screw is put, namely, rough wood work. There are two types, the cone point, and the gimlet point.



Ordinary wood screws or screw nails, as they are commonly called, are made in sizes from No. 0 to No. 30 and in lengths from ¼ inch to 6 inches. The increase in length is by eighths of an inch up to 1 inch, then by quarters of an inch up to 3 inches and by half-inches up to 5 inches. As a rule the threaded portion is about seven-tenths of the total length. The included angle of the flat head is 82 degrees.

Stay bolts:—Stay bolts are fastenings used chiefly in boiler construction. A stay bolt is quite similar to a stud since it is a rod with a thread on each end. Stay bolts are quite long, and when such a bolt is threaded into place in the boiler, each end is riveted over to give a permanent and leak-proof fastening. According to the code of practical rules covering the construction and maintenance of stationary boilers, and adopted by the American Society of Mechanical Engineers, "each end of a stay bolt must be drilled with a 3/16-inch hole to a depth extending ½ inch beyond the inside of the plates, except on small vertical or locomotive types of boilers where the drilling of the stay bolts shall be optional." The object of the holes apparently is to give some indication of a rupture by the leakage of the fluid within the boiler.

Stresses in Screw Fastenings

(a) Stresses due to Screwing up:—The stresses induced in bolts, screws or studs due to screwing up tightly into place, whether it be screwing a nut on or screwing a cap screw into place, are a tensile stress resulting from the elongation of the bolt and a torsional stress due to the frictional resistance on the thread

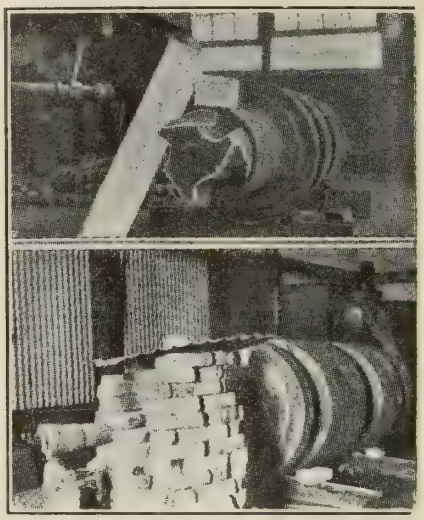
Locking Devices

Reclaiming Broken Parts Reduces Overhead

Making Salvage Pay a Profit—Locomotive Cylinders Repaired at Small Cost—Broken Castings Should Not Be Scrapped Without Investigation—Salvaging Cast Iron Rolls

By FRED E. ROGERS

TO BECOME an expert welder requires more than the mere knowledge of handling the torch. It is essential that a thorough understanding of chemical characteristics of the various metals be acquired before final success can be achieved. The article herewith explains in some detail the more important features in connection with the methods that have proved themselves efficient in oxy-acetylene welding of different metals.



Fusing Cast Iron Into Weld

Welding a thick broken casting requires melting of a considerable quantity of cast iron welding stick. When welding a preheated casting that has been bevelled to form a groove of comparatively large dimensions it is common practice to hasten the filling process by breaking up cast iron welding sticks into short pieces and throwing them into the groove where they are melted. Puddling the weld works out the oxide from the fused adding material produced from the broken sticks. Obviously, a welder can speed up welding in this manner very much. It is not uncommon in heavy cast iron welding to deposit five or six pounds of metal per hour.

Welding Locomotive Cylinder

Broken locomotive cylinders often can be repaired with the torch at less cost than by any other method. But it is useless to undertake the work unless the welder is prepared to strip and preheat the cylinder sufficiently to permit free cylinder welding and to eliminate expansion and contraction stresses. This means in many cases that the actual welding is but a small part of the labor required for the repair. It pays, however, to spare no pains to insure the success of such a welding job. The salvage in locomotive cylinder welding is more than the cost alone of a new cylinder, which is a large sum; it includes the earning capacity of the locomotive for every day saved in making the repair.

The usual cause of a cylinder break is the fracture of a piston rod which under steam pressure of perhaps 30,000 pounds or more is hurled through the front end of the cylinder, breaking the head and tearing away parts of the cylinder barrel. Sometimes the fragments are too small to bother with while in other cases they are large and can be used. When the pieces are lost it will be necessary to make a pattern for a casting to replace the lost section. This piece may be welded in place, the procedure being the same as though the original pieces were available.

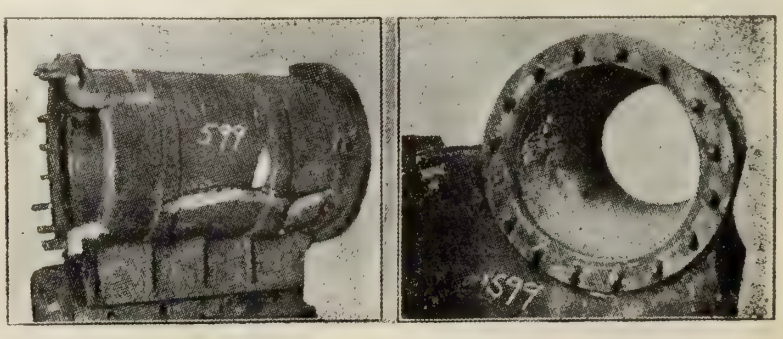
Above.—Worn roll wabbler.
Below—Roll end in pre-heating furnace.

The edges of the breaks should be beveled as well as the edges of the replacement pieces. The beveling should be done for the most part on the inside of the cylinder to insure a solid internal weld free from holes and defects.

The weld on the outside should be built up or reinforced. This can usually be done without interference with the external appearance of the cylinder as the wood or asbestos covering applied to the cylinder is from 1 to 1¼ inches thick. A reinforcement can be made ½ to ¾ inch thick without interference with the application of the sheet steel cylinder jacket.

Having the parts fitted ready to weld they should be clamped in place and the cylinder preheated by means of a charcoal fire in an extemporized brick or sheet iron furnace. When the metal has been raised to a low red, welding should be started, working, if possible, with two torches, one inside the cylinder and the other on the outside. The welders should in all cases start at the beginning of the breaks and proceed towards the edge, working on the theory that welds made in this manner tend to eliminate their own internal stresses. A practice employed successfully in reinforcing the exterior of cylinder welds requires the use of wrought iron semi-circular pieces with ears similar to the half of a pipe clamp. These should be about 1 inch wide and ¼ inch thick, having a radius of 1½ inch. They are applied successively over the break, especially on uphill welding, and fused into the cast metal helping to hold it in place and acting as a dam as the work proceeds.

When the cylinder weld has been finished it is advisable to reconstruct the furnace, put in a fresh charge of charcoal and reheat to a low red temperature to relieve the stresses and to anneal the metal. The cylinder should cool down slowly for several hours. It is, of course, necessary to put in a portable boring bar and rebore the cylinder and face the end to fit the cast iron head. It is essential, therefore, that the metal be soft and easily machined.



Old Furnace Castings

It is believed by many that furnace castings cannot be welded broken, especially if they have been long in use. Broken castings such as grate bars can be welded, however, often with no difficulty at all. An expert can weld a broken grate bar that has been in service a long time. Sometimes he will use a small amount of copper with the welding rod. This is not absolutely necessary, however. A common mistake in welding burned cast iron is in using too hot a flame. Temper the heat and watch the metal. When little spots of fluid metal are discernible, add the welding rod and get the metal flowing.

If it refuses to run clear, but persists in a "grainy" formation, shift the torch to another spot and try again. When the metal is once started welding is easy.

Salvaging Cast Iron

Cast iron rolls, used in steel mills for rolling sheets and bars, often wear out

Repairing Locomotive Cylinder.

From a book by the author entitled, Welding and Cutting.

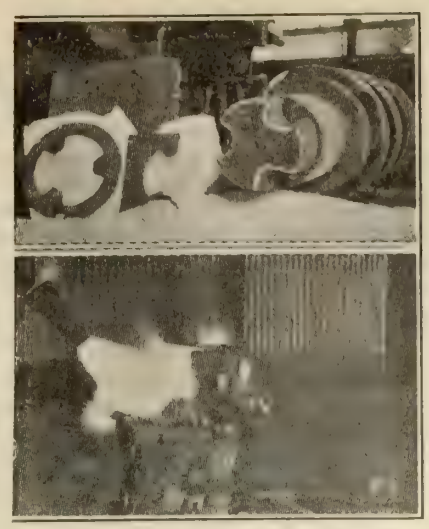
at the wabbler and before the roll itself has given out. The wabbler, so-called, is the rolling mill form of universal joint which permits the rolls to spread apart while the metal is passing through. The oxy-acetylene process is used successfully for repairing cast iron wabbler joints, the metal being built up and the shape restored as when new.

The approved practice is to preheat the wabbler and the roll, and to deposit the cast iron progressively until the original shape has been restored. A sheet metal template should be cut to the original form which can be slipped over the end of the roll and used thus to check the accuracy of the work. A template cut to the shape of one lug may be used also to advantage.

Welding Duriron

Acid-resisting cast iron such as "Duriron" may be successfully welded with the torch using filler rod of the same material. These irons are very hard and brittle, and under no circumstances should welding be undertaken without thorough preheating. The use of a good scaling powder will facilitate welding, making clean, smooth welds.

Brazing Cast Iron



Brazing cast iron in a forge fire cannot be accomplished in the same manner as steel or wrought iron. The free carbon in cast iron prevents amalgamation of the spelter with the metal, and it is therefore necessary to treat cast iron first to reduce the free carbon content and to deposit metallic copper in the surface layers. When this has been done brazing cast iron can be accomplished with ease.

The same difficulty is experienced when undertaking to braze cast iron with the oxy-acetylene torch, but the high heat of the flame enables the operation to burn out the free carbon and to secure amalgamation of the spelter with the metal. The use of certain fluxes especially those containing chlorate of potash and cupric acid facilitate burning out of the carbon and preparing the joints for the deposition of the spelter.

When a special flux which deposits metallic copper in the surface layers of metal after having burned out the excess carbon is not available the job may be accomplished by heating the cast iron until it causes the brazing rod to melt when held in contact outside the flame. Rubbing the brazing rod on the hot cast iron "tins" it, and when trimming has been accomplished, the brazing is easy.

Malleable Iron

Malleable iron castings offer a problem in welding because of the peculiarity of the metal structure produced by heat treament. White cast iron, very brittle when cold, is used for making malleable castings, the malleability characteristics resulting from heat treatment or annealing. When malleable iron is fused with the torch and welded with cast iron welding sticks, the

Above—Wabbler restored by welding. Below—Oil burner used for pre-heating roll end.

weld structure is cast iron much weaker and more brittle than the malleable iron itself. The use of malleable iron sticks somewhat improves the joint, but as the malleable iron is changed to gray iron by melting, it is advisable to avoid welding malleable iron in general. If a malleable iron piece must be repaired brazing is recommended, using bronze rods and a reliable flux for the purpose.

Reclaiming Malleable Castings

The white cast iron used for making malleable castings is melted in reverberatory furnaces, cast and annealed or malleabilized by packing in iron boxes with hematite ore or mill scale. The castings are heated and cooled in the furnace for six to eight days. White cast iron is changed by the process to the so-called malleable product by the prolonged heating and annealing process.

A simple and effective process for reclaiming malleable castings is to braze the defective part with bronze. This is objectionable, however, to some customers.

The most satisfactory method to the customer is to inspect the white iron castings for defects and to reclaim them before putting through the malleabilizing process. On account of hardness and brittleness of castings in this state they must be carefully preheated and cooled after welding. When white castings are repaired, white cast iron filling rod should be used. The subsequent process will then convert the new metal into malleable iron along with the body of the casting.

In some malleable iron foundries the parts are reclaimed after having been packed and annealed, using for the purpose malleable iron filling rod. No definite rule can be laid down for this procedure as the advisability of reclaiming will depend upon the nature of the defective part of the piece and position of the defect with relation to the parts subject to greatest stress. In general, of course, it is not considered good practice for the reason that malleable iron is deteriorated by the heat of the torch flame, and reconverted into an inferior grade of cast iron.

Hence, the situation with respect to reclaiming of malleable castings is substantially as follows:

Malleable foundries may reclaim castings in the white iron state by white iron filling rod, provided the castings are carefully preheated and cooled to equalize the stresses.

2. Malleable castings may be reclaimed by brazing, using bronze rods. The bronze produces a strong and effective repair. It is objectionable to some customers because of the obvious repaired defect.

3. Castings may be repaired after the malleabilizing process, using malleable iron or steel filler rod, but only at the cost of reducing the strength of the casting.

American malleable iron of the "black heart" form is difficult to weld with the torch. The reason is the high carbon content of the interior and the comparatively low carbon content of the malleablized shell. The latter requires a much higher temperature to fuse than the centre, the consequence being that when undertaking to weld a black heart malleable casting the inside sloughs down and falls away before the exterior can be raised to the fusing point. The "white heart" or British malleable, however, does not offer as much resistance inasmuch as the fusing temperature of the heart is approximately the same as the rod; but the joint, of course, lacks the strength and malleability of the original shell. This kind of malleable can be successfully welded with cast iron welding malleable casting and welding, therefore, cannot be recommended where strength is a prime requirement.

INCREASING LIFE OF STEEL PARTS

Every possible means of extending the life of steel parts subjected to hard wear should be studied. The tires of railway and tramway wheels provide a case in point, and users of them will be interested to learn of the success of a new process of heat treatment. Increased life to such tires can be obtained by raising the tensile strength of the steel and also by improving its structure. It is mainly in this latter respect that the new process is said to appeal.

The tire is cooled at a certain rate through the critical range of temperature by subjecting it, as it slowly revolves, to a blast of moist air. This treatment does not simply produce a surface hardening, as it can be regulated to give particularly hard and uniform structure to any desired depth. The tests which have been made with tires treated in this way gave remarkably good results. This new process has been developed by a British company.

Practical Ideas for Executives

SETTING BALL BEARINGS IN BABBITT

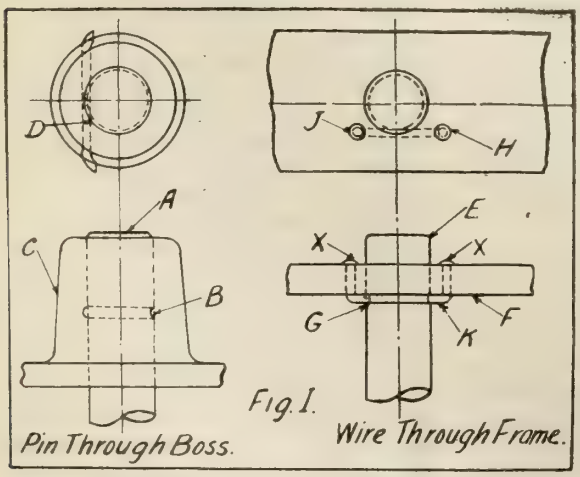
By D. A. Hampson

A line of machines was to be built and the design included a number of high speed shafts in each, to be carried on ball bearings. To bore the housings and put on end plates for each bearing would make the machines entirely too costly. The method followed was to set the bearings in babbitt and make the box divided horizontally. Cast iron blanks were turned to the exact same size as the outer rings and these were properly spaced on a mandrel—the babbitt was poured around these blanks and the pockets thus quickly produced. The machines are now in their third year and so far there has been no trouble with the practice; the babbitt was poured at the lowest possible temperature and was thoroughly anchored in the cap and box. It seems that this opens a wider field for such bearings for, ordinarily, the seat and fastenings cost more than the bearing itself to the end that competitive design hedges away from their use.

PREVENTING END MOVEMENT OF SHAFT

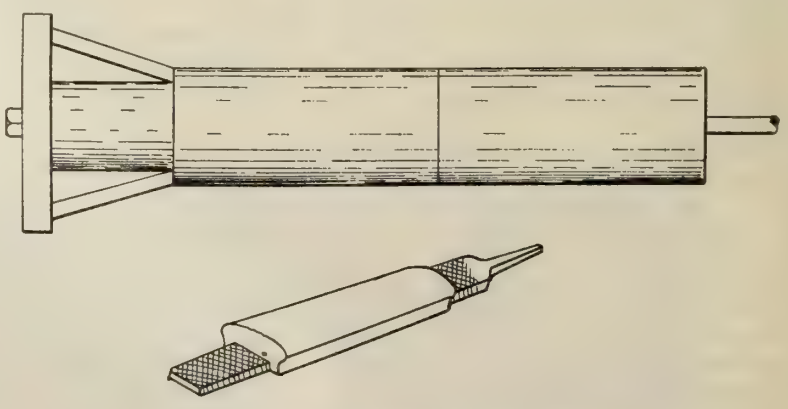
By F. M.

Two efficient methods of preventing a shaft from moving endways, where it is not intended to take direct thrust loads, are shown by the accompanying illustration, Fig. 1. In both instances a wire pin is used and the shafts are of small diameter. The illustration at the left shows two views with a pin going through the boss portion of the bearing in which the shaft runs. The shaft "A" is recessed at "B" and through the boss "C" is a pin "D." This pin hole is drilled so that at least one-half of the pin will engage with the groove in the shaft. After driving the pin in position the ends are bent over slightly to prevent the pin from falling out. With this method the shaft is free to revolve wh.. .he pin prevents the same from moving endways.



In the views at the right of the illustration, the shaft "E" runs in a flat plate "F" set edgeway, and a groove "G" is cut in the shaft. Through the plate "F" are drilled two holes "H" and "J" and the "U" shaped pin "K" is driven into these holes while the pin is sprung into the groove in the shaft. After putting this "U" shaped pin in position the ends are headed over at "X" and pin is securely held in position. The shaft is free to rotate although prevented from moving endways. One advantage this method has is that the shaft may be pulled out of position without removing the "U" shaped pin "G", as it is only necessary to spring it out of the groove to enable the shaft to be pulled endways.

HOLDER FOR SURFACE FILING



Entirely different from the general run of file holders was the one the writer saw extensively used in a printing press plant down in Connecticut. Press beds and other surfaces having areas from 15 to 30 square feet were being filed, either to obtain what they termed a smooth "frictionless" surface or to meet the cigarette-paper-and-straightedge test. And how those machinists did remove the metal! They used wooden blocks channelled to fit tightly over the files. The blocks were about a foot long, three inches wide and one and a half inches high—such a size is just about right for a good and comfortable grip and it is high enough to keep the fingers away from the work. This shape has an advantage not possessed by the other holders, in that it brings the hand down close to the work, grasping a piece practically the same as the file and thus enabling the workman to do all that he would with the bearing hard upon any certain portion of the work. Eighteen inch double-cut equaling or flat files of coarse cut are used for this work. The finish required is of a high standard. A little kink is practised that is worthy of imitation. Before the files are checked out in the shop for this work, the tool room man goes over them for high teeth and in every case he grinds the two cut ends slightly for a quarter of an inch back, doing this on a disc wheel or fine stone. This removes the high tooth that is almost certain to exist at the ends of the cut and is sure to scratch the work if left on.

BUILT-UP COLUMN PATTERN

A foundry in a remote village was asked to make a number of cast iron columns ten feet long, such as are used in the construction of commercial buildings. The columns were to be 8 in. in diameter with a 6 in. cored hole clear through and the usual rectangular base at one end. A pattern and a core box had to be made by the foundry itself, whose sole equipment toward that end consisted of a drill press and a short 12 in. engine lathe, aside from carpenters' hand tools. The pattern was made as shown herewith. Part of an old telegraph pole was secured and this was cut up into sections about 16 in. long which were faced square on the ends and turned to the required outside diameter, taking pains to make all the pieces the same. Then a hole was drilled through these wood cylinders and, after the carpenter had built the base, a ½ in. tie rod was run through the whole. When shellacked, this made an excellent pattern and at a most reasonable cost.

Preventing end movement in shaft.

METHODS OF CLAMPING FOUR PLACES AT ONCE

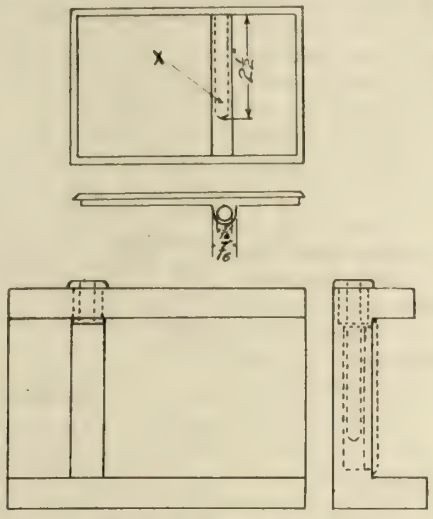
By H. M.

A rather novel arrangement having as its object the clamping of four places by simply tightening one set screw, is shown by the accompanying illustration, Fig. 1. This drawing shows a section of a gang milling fixture useful for milling the edges of the work A shown in position, a gang of cutters being used to mill a number of these pieces at once on the top edges B, while the opposite edge is likewise milled in the same fixture by reversing the work.

The particular purpose of this illustration is to show how by tightening screw C the jaws D, E, F, and G are caused to grip the work at the respective places indicated by the letters. This is accomplished through the medium of two wedge blocks H and J which are connected by a strap K. The jaws D, E, F, and G are held in the position shown by screws, these being notched and spring tempered so that the action of pushing down the pieces H and J will, through the medium of the bevel at their upper ends, cause these to be sprung so they will clamp the work which has been previously finished on the sides.

Showing arrangements for clamping four places at once

In operation the tightening of screw C forces down strap K which carries with it wedge blocks H and J. H forces outward D and E while J forces outward F and G, thereby clamping the work against the respective blocks L, N, and M. Loosening the screw C releases the work by allowing wedge blocks H and J to move upward which permits the work clamped to be removed as the jaws spring away from the work when the pressure is removed. This is a very effective means of clamping work which has been finished on the sides with reasonable close limits and a number of these units are employed in one fixture.



Fixtures of this type are suitable for multiple drilling, milling or grinding operations.

Have You Ever Had A Problem Like This?

A DRILLING PROBLEM

By H. T. Osborn

"Sometimes what appears to be a simple task," writes a reader, "turns out to be a puzzle when the job comes to be done. Here is an example of such a problem. We contemplated the manufacture of a certain article, and accordingly made up a set of patterns and jigs. On marking up the first few of the article we ran up against "it." This puzzle may prove easy to some of the readers of Canadian Machinery, and H. T. O. looks forward to such a solution.

Sketch of Jig and Piece

"The sketch will give an idea of the part, which was of bronze. When drilling the 5/16 inch hole, the drill would run out always in the same direction and bulge the side or break through at "X." The jig was quite square and packing was even tried to throw it "off square" in the opposition direction. This helped a little but not enough. The drill press table and spindle came in for attention but the trouble didn't appear to lie there.

"The bushing in the jig was square with the rest of the jig. Drilling a 3/16 inch hole first, was tried. This went right, but always on putting the 5/16 inch drill down it would run to the side. We ground the drill to various angles, without effect. The drawing shows a wall 1/16 inch thick on the outer sides of the hole. This of course was reduced as the drill ran to the side and caused a bulge, but the drill always started to run out before any distortion of the metal showed up. For some reason or other the job was dropped, and we never got a chance to experiment further. Can anybody offer an explanation of the cause of this?"

We all have problems at some time or other, some of which we cannot solve. This department is being created to act as a clearing house for ideas, and co-operation of every reader is requested. The maximum benefit can only be derived through an interchange of opinions.

Have you a problem which is yet unsolved? Or have you solved some difficult proposition, which you believe others would like to hear about?

If you can answer "Yes" to either of these queries, then by all means send your story in to the Editors of Canadian Machinery. They will not only thank you for the interest shown, but will pay for all accepted ideas. Every plant has its problems. We expect a regular deluge of replies. See that we are not disappointed.

ELECTRIC SAFETY LAMP

Electric safety lamps are coming into very general use in British mines where there is any risk of explosion. One element in their safety is the fact that they cannot be unlocked by the miner himself. A strong magnetic force has to be exerted in order to unlock the lamp, so that the battery may be taken out for re-charging. In the usual form of unlocking machine the current for the magnetic mechanism is usually applied until a certain batch of lamps is unlocked, when perhaps the current is still left on. This leads to waste of current and occasionally to damage to the lamps. In the new appliance there is a tubular magnet so arranged that when the lamp is placed on the unlocker any portion of the magnet will operate the lock. The placing of the lamp on the unlocker depresses the switch and applies the current; and when the lamp is taken away this switch automatically returns and cuts off the current. The action of this switch is automatic

FLEXIBLE COUPLING

One of the most common problems before the mechanical engineer is to provide an efficient and reliable flexible coupling between two shafts. There is no limit to the number of devices which for several generations have been designed to meet this demand, but a recent invention put on the market by a British firm proves that the field was not quite exhausted. The new coupling is extremely simple. The usual flange at the end of each shaft is cut in the form of a sprocket wheel, and a double chain is wrapped round the two sprockets. For this coupling it is claimed that it can transmit a much greater horse power at a lower cost than any other coupling of similar dimensions. It does not require lubrication; the balance is perfect; and as the stresses are equally distributed a high degree of safety is attained. For cases where heavy duty and long life are particularly desirable a certain amount of lubrication is recommended.

Recent Developments in Mechanical World

Care And Lubrication of Pneumatic Tools

PNEUMATIC hammers should be cleaned by pouring gasoline into the inlet and blowing it through by means of compressed air. An alternative method is to leave the tool overnight in a kerosene bath and next morning blow out the kerosene and lubricate well. For lubricating, a good light oil should be used. Heavy oils of poor grade are apt to cause trouble, says a writer in the Practical Engineer, and a similar light oil should be used for the pistons and valves of piston air drills. In some cases an automatic lubricator is fitted over the air inlet of the drill.

The crank chamber of the drill should be filled with a high grade grease occasionally, the filling being done by means of a syringe. Dirt sometimes causes a piston to stick. Grinding must not be attempted in such circumstances, but the cause must be removed with a piece of fine emery. The air hose should always be blown before attachment to the tool, and a hammer must never be run with the cylinder loose in the handle.

Getting Service Out of Belts

HUMAN NATURE plays an important part in getting service and longer life out of a belt. It is human nature to do things in what seems the easiest way, not always realizing it is often the most expensive and usually the most laborious, because it necessitates doing the work over and over again. This applies particularly in the case of cutting belting and joining it. Cutting the ends of a belt to put it into service seems such a simple thing that often the belt man does not give it the consideration necessary to insure the best results, and much of the difficulty with otherwise good belts is due to their not being cut and joined accurately. When you know how, it is as easy to make a belt joint which will run the same as endless as it is to do it by careless rule-of-thumb methods.

"When a belt runs wabbly or races back and forth across the pulleys," continues F. K. Douglas in a recent issue of Belts, "you are paying about twice as much as you should for it, because its life is being shortened and you are paying for power that is lost and production that you don't get. You are also repeatedly paying for unnecessary time and labor in fixing things up.

"Provided that its ends are cut square and it is joined with care, a belt can be made to run as straight as an arrow if the pulleys are lined up true. It is much easier to do it right than to do it over. This applies to making the completed joint as well as to cutting the belt. Therefore, it is best when joining a belt to do so in a way which is permanent and which ensures the belt's most satisfactory service. A prominent belting engineer has said that the following twelve points are essential for a 100 per cent. belt joint.

"It must maintain maximum strength of belt, avoid destruction or weakening of the lengthwise power-carrying belt fibres, prevent breaking the belt back of the joint, not hammer on the pulleys, not to be subject to wear or to crystallization, insure continuous, uninterrupted operation without supervision, hug the pulleys tightly and insure full transmission of power, run silently, be easily taken apart for removing or shortening, be safe against accidents or breakdowns, be easily and quickly made without special equipment, and must last for the life of the belt."

Statistics of Oil Resources

Some recently compiled statistics from various independent sources show that the probable oil resources of the world are not so limitless as was once surmised, although there is no disposition to view the future with that pessimism felt by some technologists. Oilfields, states Mr. A. Beeby Thompson, in a paper read before the Petroleum Technologists, do not cover vast areas like coal, but are represented by comparatively small and isolated pools where concentration has been induced by a combination of geological events. Existing as a liquid more or less volatile and usually accompanied by much gas, petroleum is frequently expelled with violence when its source is tapped by a bore-hole. The contained gas constitutes the agent of expulsion. It is this circumstance that enables gas and oil strata to be so quickly deprived of their flush contents instead of having to adopt laborious, lengthy, and costly mining operations as in the case of solid fuels.

Making Gas Cylinders Safe

FOR A LARGE number of engineering and mechanical processes it is necessary to store oxygen in both its liquid and gaseous forms in cylinders. Especially for mine rescue work there is a great demand for reliable cylinders of much lighter types than are usually available. Accordingly the British department of Scientific and Industrial Research appointed a committee to go into this question. This committee has issued its first report dealing with the storage of air, oxygen, nitrogen and other permanent gases. The report includes a number of recommendations both as to the composition and form of the cylinders and as to the rigorous tests which should be carried out before a cylinder is put into service. Recommendations are also made for periodical tests of the cylinders under hydraulic pressure power.

Standards For Testing Welds

The American Welding Society, 33 W. 39th St., New York City, have in print a bulletin entitled "Standards for Testing Welds." This book consists of a report of the Committee on Standard Tests for Welds of the American Bureau of Welding, which is a joint advisory board of the American Welding Society and the Engineering Division of the National Research Council. Differences in the procedure of testing welds in the past have caused widely divergent results, and comparisons are frequently impossible, with the result that the usefulness of much of the research work on record becomes limited, and in many cases the results are actually misleading. The committee feels that the need for some immediate standards is great, and the universal use of the specifications contained in the bulletin is urged upon everyone who will have to do with the testing of welds.

A new use for the oxy-acetylene blowpipe has been found in the manufacture of heat exchangers for refining petrol. Equipment of this type has hitherto been constructed with screwed connections, says Welding Engineer, which has not only been very expensive to manufacture and assemble, but the screwed connections do not approach in tightness of joint and permanence, the welded construction that is now superseding threaded pipes. These exchanges consist of twelve sections and each is made up of 112 tubes welded into tube sheets at either end, making 2,688 welds per unit. So important has welding become that the plant doing this work has its own acetylene welding shop in which three welding and two cutting blowpipes are continuously employed.

New Things in Shop Equipment

BRASS AIR GUN

A brass air gun, designed for service in foundries, machine shops, and other places where dust or chips are to be removed, has been developed and placed on the market. The construction practically eliminates air leakage. The valve is equipped with a renewal disc, providing accurate contact of the seat and takes up wear of frequent use. The gun is made by Jenkins Bros., of New York.

SHAFT COUPLING

A free-floating shaft coupling which compensates for both parallel and angular misalignment of connected shafts, as well as providing for axial movement, such as the floating of an armuture shaft. Power is transmitted from the driving to the driven hub through a floating link. A casing surrounds the parts, retaining rings preventing the hubs from slipping out. The coupling is made in sizes to fit shafts from ⅞ to 6½ inches in diameter. These are manufactured by The Kay Mfg. Co., South Norwalk, Conn.

BENCH FILING MACHINE

A bench filing machine having a reciprocating movement for using ordinary files in the regular manner, or a rotary motion for round files or special milling cutters. The table may be tilted to any desired angle for the purpose of giving draft to dies or similar pieces. The machine is driven through a three-step cone pulley. Special files having inverted teeth can be supplied so that the pressure on the work will always be downward. These machines are being placed on the market by the Boston Tool & Mfg. Co., Boston, Mass.

GENERAL TOOL-HOLDER

A tool-holder intended for general use in a lathe, boring mill, or shaper. A square hole is broached through the front end of the shank to suit the holding of square-section tool bits. Round, square, or hexagonal bars can be held to the shank transversely, and small bars can be secured in place by means of a V-block. It is thus possible to hold boring tools, drills, taps, etc., up to ¾ inch in diameter. A special clamping device is provided for holding a parting or cutting-off tool. Manufactured by the Rapid Universal Tool-Holder Corp., New York City.

SPECIAL DRILLING FIXTURE

A machine for the drilling of unusual shaped pieces has recently been developed and offered to the trade. This device is used on drilling machines to take the place of the many parallel strips and pieces of blocking required when more or less drilling of irregular shaped pieces is required to be done, and where a quantity of any one kind does not warrant making a special jig, the fixture consists primarily of a base block and two adjustable angle plates that may be placed in any position relative to each other and securely fastened. The Hartman Mfg. Co. of Hartford, Conn., are the makers.

INSIDE MICROMETER CALIPER

An improved type of inside caliper has recently been developed, which is claimed to have a wider range of possibilities than previous designs. One of the new features is that of the detachable handle, which makes the tool instantly convertible from right to left, making possible the easy reading of the graduations from either position. The spindle has a greater adjustment. Interchangeable rods are provided. The standard set, packed in a pasteboard box, consists of the inside micrometer, and adjusting wrench and five rods, giving a range from three to eight inches by thousandths. Additional rods can be furnished for measuring greater lengths, also a handle to make possible the gauging to greater depths in cylinders. These micrometers are made by the Reed Small Tool Works of Worcester, Mass.

MILLING MACHINE FOR HIGH SPINDLE SPEEDS

To take care of light milling operations on heavy parts of machinery a machine has been developed to obtain higher speed of spindle on the heavy tools required to accommodate the work. The reason of the design is that light milling operations must often be performed on heavy pieces, that are of such a size as to require a large machine to accommodate them. With this idea in view the company fitted up their No. 5C vertical milling machine so that when so ordered it can be equipped with a special three speed countershaft which permits of spindle speeds up to 1,400 r. p.m. and the use of cutters as small as 7/32 inches in diameter. This arrangement does not in any way interfere with the obtaining and using of the ordinary spindle speeds which range from 13 to 500 r.p.m. There are two shifters on the counter shaft, one for high speeds and one for low speeds. The machine has been developed by the Becker Milling Machine Co., Worcester, Mass.

SPOT-FACER AND COUNTERBORE

A very useful tool, in the form of an interchangeable spot-facer and counterbore has been recently placed on the market. The complete tool consists of the following component parts; a nickel steel holder, an externally and internally threaded nut, a high-speed steel spot-facer with milled flutes, and a machine steel pilot. The cutter is aligned correctly with the holder, by means of a ground boss that fits snugly into a hole machined in the holder. The external threads of the nut are used to thread it into the holder. The nut has two functions, one to permit the quick removal of the pilot in case of breakage; and secondly, there are several nuts, all having similar outside threads but with varying sizes of internal threads, which permit of using various sizes of pilots and tools. The end of the pilot has two flat sides and screw driver slot which permits it to be both put in place and removed from the fixture by either a screwdriver, pliers or wrench. The spot-facing tool can be used in standard Eclipse holders and pilots, through the medium of an adapter. The spot-facer and counterbore tool is made in sizes from ½ to 3 inches in diameter. The standard shank of the holder is made in No. 2. No. 3 and No. 4 Morse tapers. Spot-facers can also be supplied without the pilots. These tools are the product of the Eclipse Interchangeable Counterbore Co., of Detroit, Mich.

OVERHEAD TRAMRAIL SYSTEM

A new and somewhat novel overhead carrier has recently been introduced to the trade. It has been designed with the idea in view of reducing the time required to move work from machine to machine in the shop. The carrier may be operated by hand or electric power. The rail of the carrier may be bent to a 4-foot radius. The rails are made of a special analysis, high carbon steel which is of light section and can be bent cold on the job. The fittings employed in connection with the erection of the rail have been standardized to meet practically all requirements in connection with the installing of the carrier system in wooden, structural steel or concrete buildings. These fittings are of such design that the tramrail can easily be erected by workmen of the plant in which an installation is to be made. A system of sliding switches is provided, which makes it impossible for a carrier to run off the rail at an open switch, because of the provision of a safety stop which drops on the rail. The switches can be locked in position to prevent a carrier and its load from forcing the switch out of position. A further safety provision is made which prevents an electrically operated carrier to run at full speed against a safety stop. This is accomplished by use of a trolley insulator which provides a dead section to receive a carrier. The electrically operated carriers have ample power to carry a full load up a 12½ per cent. grade. This tramrail carrier is manufactured by the Cleveland Crane and Engineering Co., of Wickliffe, Ohio.

SELF FEED RIP SAW

A machine tool recently introduced to the trade is a new model of rip saw which embraces several new safety devices as well as a very efficient dust chute. The design of the saw enables either rough or finished stock to be sawn. The saw arbor is mounted on a frame having a vertically adjustable table. It is provided with an in-feed roller of either the corrugated or smooth design. This feed roller is used to convey the stock, not only through the saw but across the table. The arbor is so designed that saws can be mounted on it in gangs. Six saws separated by collars one-inch in width can be operated at one time. The feed provides for three different rates namely, 80, 110 and 140 feet per minute. The outstanding features of the machine are very marked, the principal ones being the quick adjustment facilities of the feed rollers, the quick adjustment and locking of the ripping fence, and the quick adjustment of the vertical table. The absorption of shocks on the feed rollers by a mechanism that also overcomes any tendency toward jerking in starting the stock through the machine, is also an important feature. The dust chute and cover form a very adequate guard for the lower portion of the machine, while the upper portion is protected by another guard. Guards even cover the feed rollers. Saws up to 18 inches in diameter can be used. Lumber up to 5 inches in thickness can be cut, and pieces 24 inches in width can be ripped. The machine may be driven with either motor or countershaft and is known as No. 65 model. The Oliver Machinery Co., of Grand Rapids, are the manufacturers.

MULTIPLE SPINDLE DRILLING MACHINE

A new multiple spindle drilling machine of the rail type has recently been placed on the market. The spindle heads on this machine, not only have a rail motion but are mounted on extending arms which permit of an in-and-out motion at right angles to the motion on the rail. The advantage of this design is that it permits irregularly located holes to be drilled and also holes with close centre distances to be taken care of. The machine is usually built with four spindles but other numbers of spindles can be provided. The design of the machine is sufficiently rugged to take care of drills 2 inches in diameter when operated at normal speeds and feeds. The in-and-out movement of each spindle can be operated independently but provision has been made to operate all the spindles together, from one end, in as far as the in-and-out motion is concerned. A counter-weight and clutch is provided for each spindle enabling it to be operated independently of the others.

Simultaneous feeding of all spindles can be controlled from one end of the machine, while independent feeding can be taken care of at the individual spindle. Quick hand-controlled vertical movement of the spindles is obtained through the medium of a hand wheel at one end of the machine. Each spindle has its own automatic stop that disengages the feed at any predetermined point. Cone pulley drive through back gears is provided, as also is motor drive through either constant or variable speed motors. A cutting lubricant pump with a distributing pipe manifold is part of the regular equipment. Cast iron floor plates, structural steel table frames, or portable tables that roll on flanged wheels on tracks led under the rail, are all optional standard equipment. The machine is adapted to take care of a very diversified class of work, as many combinations of speeds, feeds, equipment, etc., are available as well as a very varied application of the machine. The builders are the Edwin Harrington Son & Co., of Philadelphia, Pa.

HOB SHARPENING MACHINE

A motor driven universal full automatic machine for sharpening hobs, having right or left hand spiral flutes, has recently been placed on the market. The machine is also adaptable to the grinding of formed cutters, curvex cutters, or ordinary gear cutters either singly or in gangs. Two motors are used to drive the machine, a one-horse-power motor driving the spindle and a half-horse-power motor to actuate the table in its reciprocating motion, operate the indexing mechanism, drive the pump, etc. This arrangement, it is claimed, in conjunction with certain other features of design, absorbs completely all vibration. It is also stated that the consumption of current for power is reduced. Further, it is claimed that on account of the rigidity of the machine that more stock can be removed with less abrasion of the wheels, and also fast feeds can be used.

The maximum spiral at 8 inches diameter is 47 degrees right or left. The machine grinds on both strokes and indexes automatically, without stopping, at the end of each return stroke. A 9-inch grinding wheel is used, and a table speed of 28-feet per minute is used on regular work. At the end of a complete revolution of the hob, the machine automatically adjusts itself to take a new feed of a depth ranging from .0002-inches to .005 inches as may be desired. The work carrying head is so rigidly designed that except in the case of the heaviest hobs no tail support is required. The wheel spindle is carried in large bronze bearings, having oil-well type lubrication, dust proof, and provided with adjustments to take up thrust and wear. The machine is equipped for wet grinding, flooded conditions of work and wheel prevail at all times. The manufacturers state that owing to the fact that there is no idle or lost time in operation, and that the machine is substantial enough for the rapid table. The machine will sharpen hobs from four to ten times faster than the methods now ordinarily used, and accomplish this without "burning" the hob teeth. The machine is manufactured by the H. E. Harris Engineering Co., of Bridgeport, Conn.

ENGRAVING MACHINE

For some time past there has been an increasing demand for a heavy type of engraving machine for cutting dies, steel stamps, large size letters, gun work, lettering bottle moulds, and many such similar jobs in steel, brass, and cast iron. Recently a heavier design of engraving machine has been placed on the market to meet this demand. The pantograph is adjustable and has a range of 1:1 down to 6:1. The pivot bearings are ball bearing, both radial and thrust, all other pantograph bearings being formed by hardened ground and lapped cone point centres, male and female. The tracing style is held in a ½ in. collet. The adjustable scales are mounted on top of surfaces of bars, easily read, graduated, with engraved figures, giving settings for various reductions. These scales are graduated full length (20 graduations to the inch) so that any intermediate reduction can easily be obtained. For larger work, there can be furnished practically the same machine, but with a larger pantograph, the reductions being 2:1 down to 8:1.

The cutterhead is heavy and rigid and is an integral part of the heavier of the pantograph bars. The spindle 13/16 in. in diameter, is mounted on ball bearings and has a range of 1,800 to 800 r.p.m. enabling very small cutters to be used for fine work and finishing up corners, etc. Spindle speeds down to 600 r.p.m. may be obtained, by using special drive pulleys. Spindle nose has a straight hole ⅜ in. diameter with collet nut for holding cutters. When engraving work of curved or irregular contour, the forming attachment is used, having six different adjustments, in order to set it quickly and accurately in relation to the work to be engraved. The lower member of this attachment, which is directly over the centre of the spindle, carries the former block which is a hardened piece of steel of same shape as engraved surface, except in reverse. This controls vertical movement of spindle. The table is 10 in. wide, 30 in. long and 2 in. thick, at the thinnest part, and has three Tee slots ⅝ in. wide. An oil groove is planed at each edge of the table, so that oil or cutter lubricant can drain into pockets at the ends of table.

A copy holder is mounted on a bracket at the right side of the machine and is adjustable to compensate for change in reduction of pantograph. The table or longitudinal feed is 17½ in.; saddle or cross feed is 8¼ in., minimum distance end of spindle to top of table ½ in.; maximum distance end of spindle to top of table 16 in. The length of machine, front to rear, is 46 in.; width of working space overall, 68 in.; approximate net weight of belt driven machine, 1,800 lbs.; approximate net weight of motor and starter, 150 lbs. This machine is being manufactured and marketed by the George Gorton Machine Co., of Racine, Wis.

Prevent Accidents At All Cost

THE REDUCTION in number of factory accidents during the last few years has been very encouraging, but much can yet be accomplished. Take the illustration shown on this page. The correct method of handling bars incurs no additional effort or time, but a careless workman can unwittingly cause a serious injury by lowering the front of the material carried.

Not only must employees enter into the spirit of accident prevention, but the manufacturer himself should set an example by occasionally walking through his plant, pointing out to the superintendent improvements which could be made in the cause of safety.

The plant owner should enter into and not resist the spirit of fire inspection. In walking through the factory he ought not to blind himself to faults but should view things with a critical eye. He should be continually on the lookout for dirty waste, sprung spanners, loose boards in the floor, fire pails not properly filled and so on, all these being conducive to accidents.

These suggestions merely scratch the surface, but bring out the point that the owner should walk through his plant, determined if possible to find something wrong, rather than to shut his eyes to needed changes that would entail expense. It is one thing to *say* your plant is safeguarded, and another thing to *know* definitely that accidents have little chance to occur. A large manufacturing plant spent many thousands of dollars about a year ago in safeguarding one floor alone. Some grumbled at the time, these including machine operators who felt all this safeguarding was mostly humbug, but results proved the wisdom of the move. From an average of one to two accidents a day, they brought the toll down to three a year, and with other improvements they intend incorporating, expect to eliminate accidents entirely. The manager in this case is a keen-sighted gentleman who makes it a point of walking through the plant frequently, actually looking for trouble. The fact that he is now finding it difficult to discover inefficient guards, is a point in his own favor and speaks well for his perseverance. This is true accident prevention, and manufacturers would do well to follow suit.

Showing how easy it is to prevent accidents

Avoid Oil Waste

EVERY MANUFACTURING plant uses lubricating oil of some nature. The grades differ considerably, likewise the care taken of the same. An article on lubricating oils appears on the first reading page of this issue, and many valuable hints for the executive are contained in this matter.

Oil should be used, not abused. The amount of oil wasted annually in manufacturing plants is astounding. The man oiling the lineshaft is careless, tips his can before he has placed the spout in the oil hole, and waste results. If someone could follow him, catch the overflow, then show him at the end of a month the oil lost, he wouldn't believe it possible. This is only one outlet for waste, but sufficient to pound home the fact that carelessness is responsible for a large percentage of loss.

When a machine operator applies at the tool room for a milling cutter, he leaves his check as proof that he has received the tool. It is an understood fact that the cutter is in first class shape, otherwise he would not accept it. Knowing that he must return it in good condition he takes care of it, but wave these restrictions aside, then watch the damage to cutters as they come back.

Oil is a valuable fluid, and an operator should be made to understand this fact. He should realize that he must use it cimcumspectly, and once he knows that he must give an account of the amount supplied him, he will be more careful.

The manufacturer must do his part by installing suitable equipment to conserve the oil, keeping it clean, thus making it of maximum efficiency. Quality is important. A poor oil, though cheap in first cost, is expensive in the end. As one man so aptly put it. "You can't get an article good, and cheap." By close co-operation between executive and employee, considerable saving yearly will result.

E. W. Beatty, president of the C. P. R., announces the granting of three scholarships to the Toronto University. These are given for the purpose of inducing graduates of Western colleges in Canada to pursue their post-graduate studies at Varsity. This is a splendid move and deserves the hearty support of all interested in education.

Business Improvement is Very Encouraging

Few Price Changes—Undertone Bright—Gradual Betterment—Sheets Brisker—Small Tools Show Good Movement—Aggressive Salesmanship Brings Orders—Keen Competition

MANY LINES SHOW A BETTER DEMAND

PERHAPS the most interesting development in the metal and machinery situation is that the basic raw material, pig iron, is now back to the lowest price since November, 1915, and in the primary U. S. markets more business is being done.

In several departments of machine and allied trades there never was a time in the experience of the oldest men when there were so few orders. Many of them have no orders in progress or in sight. Yet at no time was there a greater feeling of optimism and confidence in the future of Canadian business.

Taken as a whole, Canadian markets show a gradual improvement this week. There have been no further price changes of importance, but in Toronto the quotation on iron and steel bars is now generally down to $2.75 from $2.90. Band steel is now quoted at $3.25 in place of $3.40. Apart from these items, prices on the Canadian steel market remain the same.

Blue annealed sheets are in slightly better demand in the Toronto field, owing to the continued open weather which has allowed more outside work. Other lines are moving, but not very briskly.

Small tools and supplies are selling at a good rate. Prices are firm, and dealers say that the entire month of February will show up to good advantage on their books.

Pig iron is very dull in Canada and further shading in price is going on. Foundries are going through a period of record dulness.

Machine tools are showing a further improvement especially on the Toronto market. This is due more to aggressive salesmanship than perhaps to better conditions. Several good orders have been closed and other enquiries which look to be worth while are on tap. Keen competition exists on this market. Montreal reports poor trade in machine tools, but this seems to be a local trouble only.

Steel ingot production in the States increased considerably last week. Part of the recent increases in steel production is in railroad material, not fresh purchases, but contracts placed late in 1921, specifications of which have only lately reached the mills. The production rate is expected to go still higher within the next two months when the spring demand becomes accentuated.

Bars, shapes and plates are down 10c in the States to $1.40 from $1.50. The latter price is still in evidence on small orders. Sheet quotations remain steady, and coke shows a stiffer undertone than it has done for some time past.

TORONTO

February 22.

"WITHOUT question, conditions are decidedly better." This statement made by a prominent local dealer, covers the market situation exactly. Business is far from normal, but it is infinitely better than it was at the end of 1921. In fact every week shows additional improvement.

Steel Market.—While no one expects a rushing trade in steel during February, the amount of business being closed is well worth while, everything being considered. Black and blue annealed sheets show the best demand of all lines, and this is no doubt due to the open weather we have been experiencing. Manufacturers are erecting smoke stacks, builders are using sheets for varied purposes and of course there are many other channels for these two lines.

Iron and steel bars have tapered off in price, being now quoted at $2.75 in place of $2.90. Some dealers are buying to hold up the price to between $3.00 and $2.90, but very little business is being closed at these high figures. A small order might only get a $2.90 price, but where the business would run up to a good figure, the $2.75 mark is easily obtained. This of course, brings band steel down to $3.25 instead of $3.40 and here again, we find a few dealers aiming for the high figure, but with little success. Apart from these changes the market is much the same as last week. Following are the new quotations:

Iron bars, base, Toronto	$2 75
Steel bars, base, Toronto	2 75
Reinforcing bars, base	2 75
Steel hoops	3 75
Tire steel	3 00
Spring steel	6 00
Band steel, No. 10 gauge and 3-1 in. base	3 25
Chequered floor plate 3-16 and heavier	6 00

Pig Iron.—The demand for pig iron continues to be very light. Foundries are inactive and as long as the chief consuming source is quiet, we cannot look for any improvement in the production end. The market is still quoted at $27.15, and as this is low, considering production costs, there is not much chance of a drop.

Non-ferrous Metals.—Copper is a little easier at present, and the demand is actually less now than it was at the close of last year, or the opening of this. Business seems to have been over-stimulated during the October-November 1921 period, and consumers were induced to buy their first quarters requirements on the assumption that prices would be higher. However, now that this theory has proved itself to be wrong, buyers are fighting shy of second quarter commitments, with the result that there is an exaggerated idea of stagnation. One large dealer claims that there is no likelihood of a lower market for April, May or June copper, and he thinks that when buyers do have to come into the market, there is a possibility of a slight advance, probably forcing the price of Electrolytic to 14c.

At present the outside market is selling copper at 13½c. delivered Eastern ports for prompt or future over the next four months. The east seems to have purchased all it requires, and export trade is quiet.

The rise in sterling has caused a serious decline in the price of copper in England, and heavy losses have been sustained by speculators in Red Metal. The advance in sterling will also make the value of tin in New York higher, but unless sterling keeps on the upward march, no decided advance in price is expected.

Lead remains about the same as last week, but the demand is not great. Spelter is a little more active, but no decided advance is looked for in this metal. Following are present quotations for 100 lb.

Lake copper	17 50
Electric copper	17 25
Castings, copper	17 00
Tin	34 50
Spelter	*7 25
Lead	6 75
Antimony	8 00
Aluminum	27 00

Scrap Metals.—Prices have not changed since last week, and demand still remains very light. Until foundries become more active, we cannot expect much improvement in the iron lines, and as far as the other articles are concerned, they are low in both price and demand. Following are present quotations.

Copper, light	8 00
Copper, crucible	10 50
Copper, heavy	10 50
Copper wire	10 50
No. 1 machine composition	8 50
New brass cuttings	6 00
Red brass turnings	6 00
Yellow brass turnings	4 75
Light brass	3 50
Medium brass	4 50
Scrap zinc	4 00
Heavy lead	4 00
Tea lead	3 00
Aluminum	10 00
	Gross
Boiler plate	9 00
Heavy melting steel	12 00
Axles (wrought iron)	20 00
Rails (scrap)	12 00
Malleable	12 00
No. 1 machine cast iron	19 00
Pipe, wrought	6 00
Car wheel	18 00
Steel axles	18 00
Mach. shop turnings	6 00
Stove plate	16 00
Cast boring	6 00

Machine Tools.—A decided improvement has taken place in this market. Several good orders have been closed during the week. The chief feature regarding this business, is that it has all been of the "Go-Get-It" variety. In other words, dealers had to go after it

good and hard, before they managed to close.

A peculiar point came up this week, and one worthy of careful consideration. A certain dealer had travelled quite a few hundred miles in order to try and secure a much desired order. Everything seemed O.K. The engineering department was satisfied, in fact everybody concerned seemed satisfied, except the purchasing agent. "We will give you this business if you'll meet such and such a figure," he remarked, naming a ridiculously low price, and the dealer's reply is worth recording.

"Do you know what you are unconsciously trying to do," he commenced. "You're trying to make honest men, dishonest."

"What I mean in this," continued the dealer. "I've travelled a considerable distance because I wanted this order in the worst possible way. I realized that competition would be very keen, and shaded my prices accordingly. I'm down to the lowest possible figure now, that is if I give you the proper quality of goods suitable for your work. I could give you a lower figure, supply you with seemingly similar material, pleasing you temporarily perhaps, but being dishonest nevertheless."

The dealer secured the order at his own figure and the point brought out is worth consideration, viz., that you may squeeze a purchase through at a very low figure, but are you getting quality at the same time? It may be a buyer's market, but the buyer should be sure he hasn't set a trap for himself by his keen bargaining. Get as low a price as you can by all means, but make sure the quality is there.

One dealer reports there is a tendency to buy for a longer period, rather than hand to mouth variety. In such cases a small margin of profit only is allowed, thus protecting both dealer and buyer. Second hand tools are still moving, these being even more brisk in some cases than the new tools.

Small Tools and Supplies. — A still further improvement is noted in this line. Every week shows business a little better and dealers feel that this steady upgrade movement will continue until the normal point has been reached. This will of course be a slow and gradual process. Nothing special is featured, the demand being general, and even the locality of orders is pretty well scattered.

Miscellaneous.—Oils and greases are still quiet, manufacturers purchasing only for immediate needs, and the same story holds good regarding waste and wipers for industrial purposes. Steel pipe is selling at a fair rate, but as soon as Spring opens up the demand in this line is expected to increase. Considered in its entirety, the local market shows a gradual improvement.

In the March 2 issue will appear an article on Precision Instruments. Watch for it.

Montreal

February 22.

THE GENERALLY quiet conditions that have prevailed since before the first of the year in business circles do not appear to have changed much in the last week. Trading in steel is very quiet.

The channels through which steel is usually marketed do not present any prospects that give promise of early business. In the case of merchant bars, the demand has fallen off to an alarmingly low point. One does not have to look far for the explanation. The largest consumers are manufacturing plants and these firms are operating at a small percentage of their capacity.

Iron and Steel.—These lines show one of the quietest periods in the last decade. The base price of steel is claimed to be below the point where a reasonable profit can be obtained. Mills are looking up orders very aggressively in an endeavour to keep their organization together. Even these aggressive sales efforts have not been productive of good results. At present the productive capacity is far in excess of the consumption even under normal conditions.

The prospects for an increasing demand in structural shapes are good. Locally there will be a great deal of building. The plans that are being seriously considered are good grounds for stating that the local building contractors will have a busier season in 1922 than they have had in many years.

Sheets are not moving as rapidly as they have been in the last few months. The present lull is not expected to last as the demand for this class of material comes from a wide and representative range of consumers. It is expected that seasonal demand will soon increase.

Plates are very quiet. A better situation in this department is looked for presently. Heavy sheets and the thinner plates are being consumed in a multitude of ways in the manufacture of containers, and as conditions improve outside the metal industries, the demand for this material will increase.

Pig Iron.—The market for pig iron is in the same condition as it was last week. There have been no price changes and the demand is not any better. The foundries have not picked up any business lately that would alter the quiet conditions prevailing. All the buying that is being done is of the hand-to-mouth variety. Prices are not attractive to the producer, and it is questionable if any of them would be willing to contract very far in advance.

Machine Tools and Supplies.—The machine tool business is also very quiet. Any sales that are being made are for single tools. The railways, generally large purchasers of machine tools, have not come into the market for some time. A large surplus of machine tools was accumulated during the war years, and this is only being slowly absorbed by the small amount of work being done in railway shops, owing to the falling off in traffic.

The small tool business is not as good locally as it has been for some months past. There is, of course, a small amount of business, but during the last week it has only been nominal. Prices are gradually falling and from time to time additional discounts are given. These represent part of the saving made in production, and the manufacturer in the face of poor business and keen competition is taking only a fair profit, and is passing most of his additional savings on to the consumer.

Non-ferrous Metals.—The quotations on non-ferrous metals are somewhat weaker this week. London markets show quite a falling off in price. In fact quotations are lower to-day than they have been at any time in the last ten years. A week ago they reached the low point of last August. The further drop has been made since. The business being closed is very poor, and the call for ingot copper and ingot lead is light. More or less scrap is being consumed, but this market is also very weak.

Pittsburg

February 22.

PITTSBURGH, (Special to Canadian Machinery)—Steel ingot production underwent a sharp increase last week, as it can be estimated on the basis of trustworthy reports that the rate was 28,000,000 gross tons a year. This is well above the highest rate attained last autumn and shows a sharper increase than occurred in the earlier weeks of last year. Our report a week ago pointed out that production increased during January at a greater rate than had been suggested in the statements made public by the mills as to the condition of the market.

Steel Production.—Part of the most recent increases in steel production is in railroad material, not against fresh purchases, but against orders or contracts placed late in the old year, specifications against which have only lately reached the mills. This includes some rail business, being filled at the Edgar Thomson works, in the Pittsburg district, and in the Chicago district, also car material, being produced in the Chicago district, against freight car orders placed in November. Apart from this railroad business, the production of ingots is for speedy rolling into finished products, against orders booked from day to day for prompt shipment, and thus on the whole the rate of steel ingot production reflects closely the state of buying.

A general survey is of interest, to show the swing. The slump in production last spring and summer, when stocks of steel and of manufactures of steel were being liquidated, brought the ingot production rate down to 11,000,000 tons a year, in July. Then production mounted, and the rate was 23,000,000 tons a year in October and November, measuring the size of the autumn consumption, as stocks were then fairly well liquidated. Early winter brought

a recession, and the rate the last week in December was under 18,000,000 tons. Now the rate is up to 28,000,000 tons, showing a very sharp increase in seven weeks, and a 20 per cent. gain over the rate of last autumn.

The full force of the spring demand is of course not felt as yet, and thus the prospect is that production will reach still higher rates in the next couple of months. Presumably there will be a tapering off towards summer, but there is no reason apparent for demand not showing a still higher tide next autumn, for fundamental conditions are improving continually and perhaps no more slowly than one should expect.

Requirements Widespread.—Demand for steel is widespread, almost universal. No consuming line is conspicuous for the size of its demand, and no line is conspicuous by its absence from the market, excepting alone the agricultural implement trade. No part of the country is buying much more heavily than other parts, but the agricultural sections, in general, show much less demand than industrial sections. The reason for this is well understood, the very low prices realized by farmers for what they sell, as compared with prices they are asked for things they normally buy.

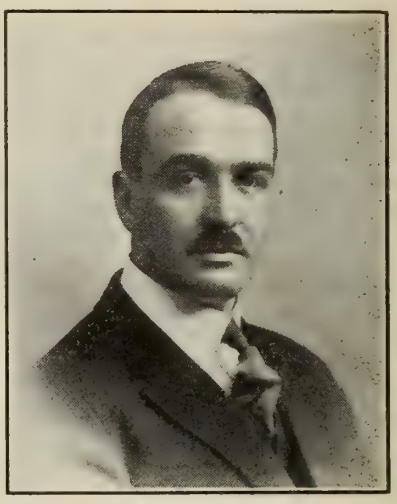
The buying, except in the case of rail contracts and freight cars, in the case of the railroads, and a moderate sprinkling of large construction jobs, is all of hand-to-mouth character, and for very prompt shipment. It is not a case of buyers "holding off" because they are suspicious of steel prices. The buyers are buying as much steel as the state of their respective lines of business requires. They have no occasion to buy for forward delivery, since they feel assured that when in future they may need steel they will be able to get it. The large productive capacity now existing seems to insure that. Thus, when ingots are produced at the rate of 28,000,000 tons a year, the estimate made for last week, this is 10 per cent. more than the production in 1910, when the steel mills were fully engaged and all consumers of steel were busy, but it is only 53 per cent. of capacity. The natural presumption is that consumers will be as busy as they can be consuming steel before mills are entirely engaged in making steel.

Steel Prices Sagged.—Bars, shapes and plates are now quotable at 1.40c rather than at 1.50c. This does not mean that the market has declined by any such amount in a week, whereby much smaller orders than formerly can now be placed at 1.40c, a price which a couple months ago was done only on the largest and most desirable orders. The 1.50c price is still in evidence, but obtains chiefly on carloads and similar small lots. The range of the whole market has been quotable as 1.40c to 1.50c for some time past, but formerly 1.40c was a special price. Now it is rather the 1.50c that is the special price.

So far as can be ascertained, mills have not gone below 1.40c except in an occasional instance, perhaps, when a mill is at a freight disadvantage. Eastern mills have been doing 1.50c to 1.60c f.o.b. mill, making delivered prices that would require a price of less than 1.40c for a Pittsburg or valley mill to meet, usually these mills do not attempt to get orders in the east when the eastern mills make their special prices, just as long ago they had to leave the Chicago market largely to the Chicago mills. This represents quite a change from the old times when "Pittsburg plus" made the market for practically the entire country.

Sheet Prices Steady.—Sheets continue to be firmly held at 2.25c for blue annealed, except in the lighter gauges, 3.00c for black and 4.00c for galvanized. Nails continue in about the same position as formerly, with $2.50 maintained for the general run of the trade and $2.40 done with particularly large distributors. Standard steel pipe is being shaded 2½ to 5 per cent. by independents and as more often than not the independents give an extra 2½ per cent, there is no particular prospect of the leading interest changing its regular prices.

Pig Iron and Coke.—Furnaces feel that pig iron is lower than it should be, considering costs, while at the same time each furnace that is in operation wishes to sell every ton possible, the result being that sometimes pig iron looks strong and sometimes weak. Quite a test was made in the past few days in foundry iron, disclosing this condition, that all the furnaces but one refused to go below $19 valley, while one valley furnace did sell at $18.75, and some of the furnaces that held ordinary No. 2 rigidly at $19 were willing to sell No. 2X at precisely the same price. Then there are at least two furnaces, having a slightly lower freight to Pittsburg than the valley rate of $1.98 that hold to $19 at furnace, which would give the Pittsburg consumer iron at less than the equivalent of $19 valley, but not as low as $18.75 valley. With one valley furnace having sold at $18.75 the market seems quotable at $18.75 to $19 valley, against $19 formerly quoted.



Connellsville coke, which showed a stiffer undertone a week ago, appears to have advanced sharply, for it is positively asserted that one lot of 75 carloads of prompt furnace coke went at $3.25 and a day or two afterwards 50 carloads went at $3.50. Whether such prices will hold if demand relapses to its former small proportions is a question. Dover furnace, Dover, O, which blew in a few days ago, contracted to July 1 at $3.25. Offerings of foundry coke at $3.75 seem now to have disappeared entirely, leaving the market at $4.00 to $4.25 for spot or prompt.

The Cincinnati Milling Machine Co., Cincinnati, has published a 32-page illustrated booklet in which the use of milling machines in locomotive repairing is described and illustrated. Data are given on machining operations on various locomotive parts. In addition specifications of the machines are given.

EXPECTS GOOD BUSINESS BY JULY

H. H. HINES is now district sales agent for the Consolidated Steel Corporation, with office in the Royal Bank Building, Toronto. Speaking to Canadian Machinery on the steel situation, Mr. Hines said, "that on the whole, the steel market had not shown as marked an improvement as many had hoped for with the turn of the year, but in spite of this fact, their tonnage for January was larger than any month in 1921."

"Opinion is still divided considerably," continued Mr. Hines, "regarding the prospect of a big buying movement in the spring. So far as our firm is concerned, we are looking for a considerable demand by the first of July.

H. H. Hines, district sales agent for The Consolidated Steel Corporation.

"Indications point toward spring business of some considerable volume and we particularly desire for special reasons, that standard commodities will go lower than the prices now ruling, but in spite of our desire, we believe such a condition is impossible, until further marked changes take place in the fundamental governing costs.

"We cannot see where these changes can occur in the near future for prices are undoubtedly dragging bottom at the present time, and we do not look for any lower figures to rule generally. In fact we are rather inclined to think a stiffening tendency will occur at the first real indication of improved demand."

For four years Mr. Hines was with the Imperial Munitions Board at Ottawa, as assistant purchasing agent. In 1919 he joined the sales staff of the National Acme Co., Montreal, and in December, 1921, resigned to accept a position with the company he now represents. He comes to Toronto with a varied experience, and a keen knowledge of existing market conditions and is a Canadian by birth.

The Dominion Motor Show will again be held at the Motordrome, on Sherbrooke St., Montreal, during the week of Feb. 25 to March 4. Three-fourths of the space has already been reserved.

SELECTED MARKET QUOTATIONS

Being a record of prices current on raw and finished material entering into the manufacture of mechanical and general engineering products.

News From the Industrial Field

McColl Bros., 67 Bocelier St., Ottawa, will erect a warehouse and three storage tanks.

Mr. J. Vance of Coppin, Ont., is in the market for complete saw mill equipment. Estimated cost $25,000.

The Dover Oil Company, Bell River, Ont., are in the market for equipment, tanks, piping and drilling equipment.

The Sunshine Soap Co., Hagersville, Ont., with Walter Diffie as manager, will build a factory at that town to cost $60,000.

The Board of Commissioners, Edmonton, will spend $300,000 on improvements and additions to its waterworks plant.

The Greb Shoe Co., Kitchener, are in the market for $25,000 worth of special shoe making machinery and equipment.

The erection of a garage at a cost of $18,000 on Kent Street. Lindsay, Ont., is contemplated by Mr. Fee, Montreal, Quebec.

At a recent meeting of the Montreal Harbor Commissioners, J. F. Simmons was appointed to the position of Harbor Master of the Port of Montreal.

The actual outlay on business and engineering construction has increased since the end of the war 323 and 310 per cent. respectively.

The Board of Education, Fort William, Ont., have adopted a resolution for the erection of a school at a cost of not more than $90,000.

The City Council of Toronto passed by-laws for raising $2,500,000 by debentures for expenses and new buildings required by the board of education.

The factory owned by the Leggett & Platt Bed Spring Co., 900 MacDougall Street, Windsor, Ont., was recently damaged by fire with a loss of $12,000.

Fire losses in Canada during the week ending February 8 are estimated by the Monetary Times at $756,300 compared with $1,363,000 the previous week.

The Catholic School Commission, Montreal, have obtained the approval of the Quebec Legislature for the borrowing of $2,300,000 for the construction of schools.

Mr. Stern, of the Canadian Tank & Pump Co., says that business is exceptionally brisk in their line. Good sales are being closed, and from their experience, he feels things are decidedly on the up grade.

Montreal fire losses since the first of the year approximates upwards of $37,000 each day for every day this year. This is nearly 300 per cent. higher than that of the corresponding period of 1921.

There is a report current to the effect that the manufacturing plant of the Asphalt Block Company of Walkerville, Ont., will shortly re-open. The plant has been closed for several years.

General contracts for the erection of of shed costing $15,000 for Canadian Ramapoo Iron Works, Stamford, Ont., has been awarded to the Robertson Construction Co., Niagara Falls.

The president and managing director of the Calgary Gas Co., has stated that the company has planned to spend some $50,000 in building new wells next summer for procuring a new supply of gas.

Yarrows Limited, Vancouver, B. C., has been awarded the contract for repairs to the Government steamer Givenchy which struck and was submerged for six weeks near Bella Bella, three months ago. The work will cost about $10,000.

The Wallace Shipyard, Vancouver, B. C., was awarded the contract for the remodelling of the steamer Admiral Farragut, the company being the lowest bidder at a price of $63,250. The work will last 60 days.

The Abitibi Power and Paper Co., plant at Iroquois Falls established another record output during the first week of February with an average daily production of 455.38 tons against 459.13 tons the week previous.

Commenting on the possibility of a strike among the coal miners of the United States, H. A. Harrington of the Coal Exchange of Canada stated that a lengthy duration of suspended operations, would result in considerable inconvenience to users of American coal in Ontario. Canadian authorities will likely take steps to minimize coal shortage.

The Magnolia Metal Co., of Canada, located at Montreal have completed their new factory and offices on Shannon Street and are now fully equipped for smelting and refining white metal alloys. The equipment includes new reverberatory furnaces and facilities for chemical research, etc.

What are Canadian banks doing to make possible the financing of Canadian exports to continental Europe? Poland is buying millions of dollars' worth of machinery, motors and machine tools in the United States.

It is announced unofficially that the British Empire Exhibition, advertised for 1923, will likely be postponed until 1924. A British mission is now in South Africa working up interest in the exhibition, and is due to arrive in Canada for the same purpose on August 12th next.

The Department of Public Works, Ottawa, plan extensive harbor improvement, including the deepening of the harbor at Goderich and improving and making additions to the docks. The cost of the work is estimated at $50,000.

The Standard Steel Construction of Welland has secured contracts for the construction of three swing bridges, one for the Trent Canal in Ontario and the other two for locks 1 and 2 on the Welland Canal at Port Dalhousie.

Application will be made by the city of Toronto to the Provincial Legislature for authority to pass a By-law to raise $1,012,579 for the laying or renewal of such pavement in connection with construction, repair and renewal of the street railway tracks of the Toronto Transportation Commission.

The London and Port Stanley Railway, Phillips Street, London, is in the market for a derrick clam shell bucket and unloading and operating equipment for coal unloading depot at Pt. Stanley. Estimated cost $25.000.

The erection of a convention hall on the Victoria Park property at the corner of 17th Avenue and Second street, East, Calgary, to cost approximately $143,000, has been recommended by manager E. L. Richardson and the executive of the Calgary Exhibition Board. The project has been approved by Mayor Addison and many other citizens.

A reduction of approximately 40 per cent. on all farm machinery has been announced by the United Grain Growers Limited. It is further stated that they have based the spring prices on the implement price prevailing in 1915. Generally speaking the prices of farm products are down to the 1915 level.

In accordance with the judgment and order of the Board of Railway Commissioner of industries. **The Ford com**rate of exchange in connection with shipments of freight between points in Canada and the United States, from February 15 to February 28, inclusive, will be 4 7-16 per cent., and the surcharge on the said traffic will be three per cent. The rate of surcharge on International passenger business will be based on four per cent. exchange.

During the last year Hamilton secured 24 new industries according to the report of Mr. T. W. Kirkpatrick, Commissoiner of industries. The Ford company has established its headquarters in Hamilton, but has not yet commenced manufacturing. This showing is regarded as highly creditable in view of the industrial condition prevailing during 1921.

Plans connected with a demand for Hydro-Electric power in the Calumet channel of the Ottawa river at Bryson, Quebec, have been deposited by the Ot-

tawa Steam and Electric Power Mfg. Co., with the Minister of Public works at Ottawa and the Land Registry office at Bryson disclosing the fact that the company is considering future expansion.

It has been announced that the sum of $400,000 has been provided for the remodelling of the old Board of Trade building at Toronto, to house the offices of the Toronto Transportation Commission and the Toronto Hydro Commission instead of going ahead with the construction of a new office building.

The big marine boiler order received by the Engineering and Machine Works St Catharines, Ont., will keep the boiler department of the plant going night and day for the next three months. The manager stated his plant was fully manned at present. Signs of improving business are also being shown in other industrial plants in the city and district.

The civic council of Peterborough, Ontario, will make an effort to secure from the Dominion Government an additional $41,000 towards the cost of constructing the Hunter Street over-head bridge. On the original cost of $300,000 for the bridge the Government would need to contribute one-sixth, or $50,000. Up to the present time the cost of constructing the bridge has been $550,000.

The Department of Trade and Commerce has recently decided to concentrate its efforts to induce industrial executives of the United Kingdom to consider the Canadian field as a theme of operation. With that aim in view a booklet has been prepared by the Department of Trade and Commerce presenting information about Canada's resources, transportation system, labor conditions and industrial activity.

Mr. H. B. Bousette, director of the Commercial Intelligence Branch of the Department of Trade and Commerce, speaking at the Rotary club in Peterboro recently, urged the Rotarians to take an interest in export trade and direct their influences to advancement of Canadian products in other lands. The speaker stated that twenty-two agents are busy in foreign countries opening up connections for Canadian firms. The cost of this work last year was $230,000.

Arrangements have practically been made by the Quebec Harbor Commission for the erection and operation of an oil fuel plant in Quebec similar to the plants now in operation in Halifax and St. John. The idea is that the city of Quebec will be the main fuel station on the St. Lawrence for all oil burning vessels. The commission plans to erect a 225,000 gallon tank on the property of the commission and this will be completed by May 15th next.

Harbor Officials are of the opinion that navigation will be later than usual in starting this year. One stated that instead of there being about 17 miles of open water between Montreal and Quebec, as is usual at this time of the year, there is only about 13 miles, while from Montreal the ice carriers extend to Pont Neuf, which is a much greater distance than usual. April the 15th is the day set to see the real opening of navigation.

In order to be able to meet the United States competition the charges for the use of Canadian dry docks on the Pacific Coast have been reduced about one third or back to their pre-war level, for the next six months, at the end of which period the question of dry docks charges will have been considered and definitely settled by the Government. The docks at Esquimalt and the floating dry dock at Prince Rupert are affected by this reduction.

Engineering and Machine Works of Canada, St. Catharines, Ont., have announced the receipt of a fair sized order. J. E. Waterhouse, the managing director, stated to Canadian Machinery, that they had closed contracts for ten Scotch type marine boilers, 14 ft. 7 in. in dia. x 10 ft. 8 in. long, and for a working pressure of 180 lbs. Eight of these are for Three Rivers and two for Collingwood. As delivery is required this spring it has been necessary to put on a night shift.

Facts and figures about Canada have been prepared in such form as to attract the attention of the British manufacturers to the field that the Dominion presents to their energetic enterprise. The establishment of about 700 branch plants by American companies while highly desirable, is a sharp contrast to the comparatively small interest shown by British manufacturers. However, there is evidence that many British manufacturers are considering the matter of beginning business in Canada.

As a result of a conference between the Premier of Ontario and the members of his cabinet, the mayor and city council of Fort William and representatives of the Great Lakes Pulp and Paper Company, an agreement may be arrived at which will result in the construction of a pulp mill and paper mill at Ft. William. Both Ft. William and Pt. Arthur are vastly interested economically in the establishment of the industry and the distribution of Nipigon Power at low rates.

Speaking on the advancement of trucks, at the present time it has been found that the motor propelled vehicle travelled 25% longer distance, made 183% more round trips, 48% more corn, and 50% more wheat and that from 45 to 50% of the ton cost per mile of wagon hauled grain. One farmer has found that the cost to deliver 28 cans of milk by truck was $2.52 comared with $7.56 delivered with horses. This certainly speaks well of the progress of the automotive industry and it may be a good sign for cylinder re-grinding.

China with its 375,000,000 people, is coming to desire and therefore need, many of the accessories of the West. Canadian firms who go to seek business in China are getting it. That country imported about $1,000,000,000 worth of goods in 1920 and will import a great deal more as time goes on. China is evidently sending more to Western nations than to Japan, as trade figures indicate. Steel and machinery of all kinds are in demand in China and electrical goods in considerable quantities.

The business of the Collins Manufacturing Co., of Toronto, and Never-Fail Products Limited of Hamilton have been combined. The new organization will be known as the Collins Never-Fail Products Limited. They will carry on their production and largest operations in Hamilton in their modern factory at 1322 Burlington Street, East. The new company will develop to a much greater degree in the line of metal supplies and products before made by the Collins Manufacturing Co. The line of sprayers will be continued as well as other novelties made by them. C. W. Collins will be president and general manager.

When the estimates to provide for continuance of the Canadian Government Merchant Marine come into the House of Parliament this year they will not, it is understood, come from the Minister of Marine and Fisheries, as has been the case in former sessions, but instead from the Minister of Railways and Canals, Hon. W. C. Kennedy. It is believed almost a score of the C. G. M. M. vessels have been lying idle because of the shortage of cargoes. When the annual statement is brought in there is little likelihood according to reports current, of anything but a loss on the year's operation being shown.

Still another Buffalo concern has decided to locate a branch plant at Bridgeburg, Ontario. Announcement has been made that the Acme Pattern and Tool Co., of New York has leased the Thrope factory on Courtright Street and will manufacture knitted goods, etc. The concern will eventually construct a plant of its own if this Canadian branch proves to be a success. This is the third Buffalo plant to establish a Canadian branch at Bridgeburg, since the first of the year, the other two being the Silk Voile Manufacturing Co., and the Dominion Rotogravure. The first company now has a force of sixty working at its Courtright street branch, while the second is installing its machinery in the Jarvis Street Building it has leased.

Further strength in changes of Canadian exchange on February 16th makes the Canadian dollar worth $96.43 cents, the highest price for over two years. One year Canadian dollars were selling in New York for 12% discount. While strength in Sterling exchange is thought to have been primarily responsible for this increase in the value of Canadian money, financial authorities attribute the steady recovery of the Canadian dollar mainly to the excellent trade conditions of the Dominion. Expansion in Canada's trade, while exports from the United States through the Dominion have been declining sharply, seems to be the best explanation for the improvement in Canadian currency in the New York money market.

In February 16 issue appeared an article entitled "Producing Work at High Speed." We should have mentioned that we were indebted to the Gisholt Machine Co., Madison, Wis., but unfortunately this was omitted.

The activity displayed by the Quebec Provincial Government in the building of iron bridges has greatly contributed to the solution of the problem of labor in the provinces, says the report of the Department of public works and labor. The Batiscan Bridge, which completes the Montreal-Quebec highway, was regularly opened for traffic on the first of November last. This bridge is not only solid, but it is remarkable from the standpoint of civil engineering owing to the difficulties met with while it was being built. It is 1,219 feet long with an open roadway of 18 feet of re-inforced concrete and a movable span for the purposes of admitting ships.

At least one hundred more men will be taken on in the beaverboard plant at Thorold as a result of a decision of the company to transfer all their orders for beaverboard, which ordinarily would be cared for by their New York mills, to the mill at Thorold. The mill will be speeded up to full capacity as soon as possible to care for the additional orders. Manager superintendent Robertson stated that it was the intention of the company to manufacture all their beaverboard in Thorold hereafter. The business now diverted by reason of the shut down of the New York plant would not be returned to that unit when repairs were completed unless demand for beaverboard so increased that Canadian mills could not take care of it.

Possibilities are said to be strong for the sale by the city of Port Arthur, of a block of Hydro Power in the neighborhood of 5,000 H. P. to the Palatine Corp. for use in the block service which they have acquired from the Port Arthur harbor front. Considerable renovation to the old plant has been done by the Hancock Construction Co. of Fort William, and it is stated that the general repair of smelting machinery will be carried on early in the Spring. It is stated of the condition of the plant that it could be put in readiness for operation in less than three months. At the present time the plant is equipped with a steam power plant but it is said that this will be augmented in a considerable degree by electric power. Electricity will in all likelihood be used for the furnaces and in this connection an expert engineer of the company's staff, is at present making an inspection of smelting plants equipped with electric furnaces in Sweden

Cut Gear Specialists

Let us handle your gear requirements

Gear Data For Your Note Book

Cut this out,—more coming later

DEFINITIONS AND RULES FOR GEARS

from The HAMILTON GEAR & MACHINE CO., Toronto

Diametral pitch (D.P.) of a gear is the number of teeth per inch of pitch diameter.

Circular pitch (C.P.) of a gear is the distance from centre to centre of teeth measured along the pitch circle.

Circular pitch equals 3.1416 divided by Diametral pitch.

Thickness of tooth at pitch line is half the circular pitch, or equals 1.5708 divided by the D.P.

Addendum is the distance from pitch circle to outside of gear.

Dedendum is the distance from pitch circle to bottom of tooth.

Clearance is dedendum minus addendum, or equals 0.157 divided by the D.P., equals 1-10 thickness of tooth.

If outside diameter (O.D.) of a spur gear is given to find diametral pitch, add two (2) to number of teeth and divide by the O.D. in inches. Reverse process to find O.D.

Pitch diameter equals the number of teeth (T) divided by the Diametral pitch, or it equals the number of teeth multiplied by the circular pitch and then divided by 3.1416.

Distance between centres of two gears is half the sum of their pitch diameters.

Write us for Quotations.

15,000 THREADS

Cut with One Set of Geometric Thread Chasers on These Radiator Caps—a German Silver Casting—Not a Very Clean Casting, Either

Geometric Adjustable Thread Chasers are a small part of the Opening Die Heads and Collapsing Taps in which they are used, but they are an important part.

They stand up to the work—doing even more than is claimed for them, when rightly used.

"No sign of wear on the cutting face of a set of Geometric Chasers after cutting threads on fifty pieces of work, and from all appearances good for many hundred pieces without regrinding."

Such factory reports make Geometrics the Standard wherever they go.

List of Directory of Dealers will be found above Advertising Index

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

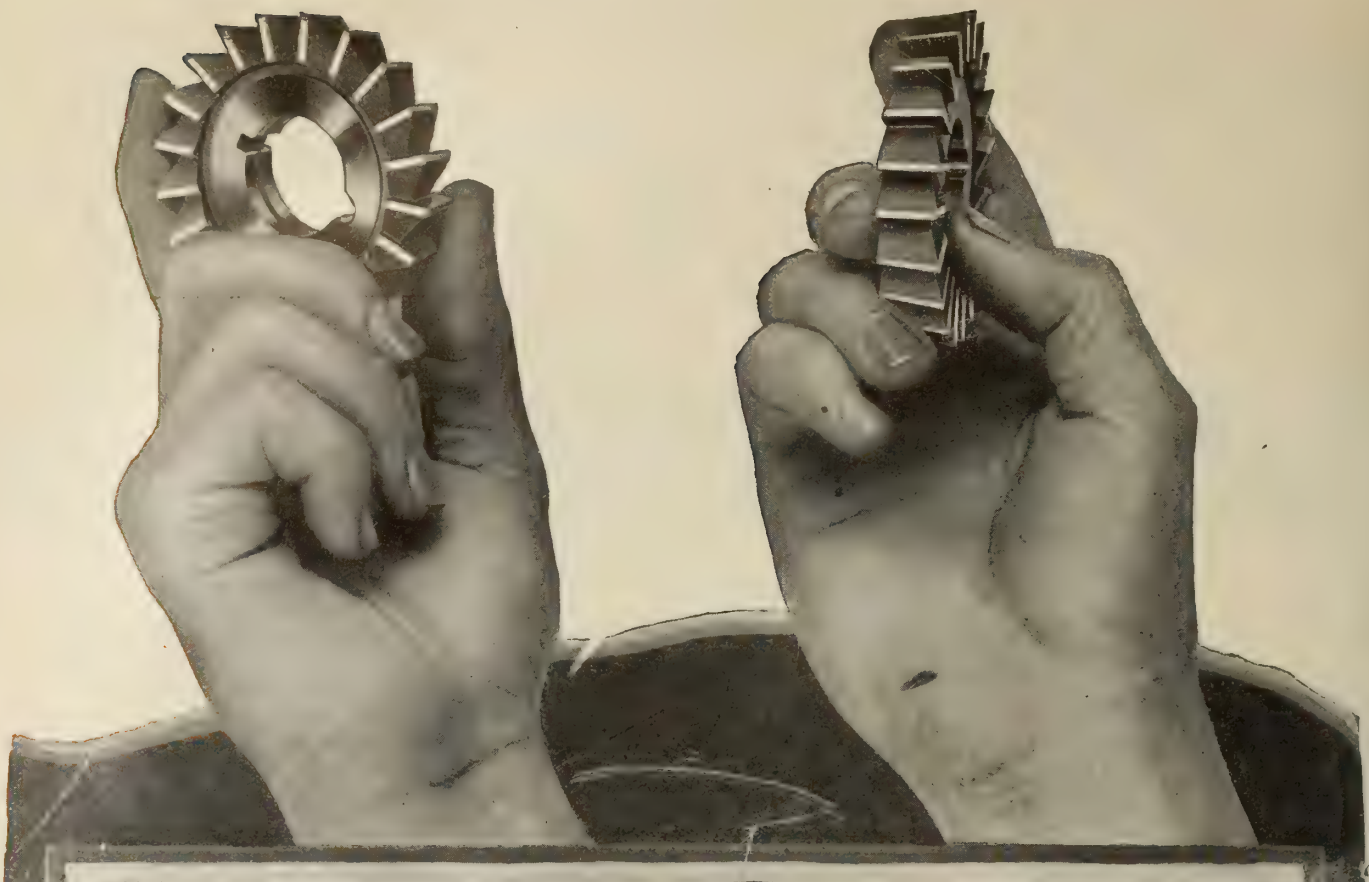
"HYDROIL" INTERNAL GRINDER

PRODUCTION INCREASED
BELL-MOUTH ELIMINATED
ACCURACY
FINISH



"Hydroil" Grinders have opened up an entirely new era for the grinding of internal surfaces thru high table speeds up to 30 odd feet a minute, or on short strokes (1-2 inch) reversed 300 times a minute without shock or hand operation, permitting the use of the full face of wheels varying from 3-4 to 2 inches, determined by application.

"Hydroil" Grinders will remove one cubic inch of hardened steel a minute with an average wheel wear of 17th of the material removed in roughing operations.

There are many other productive, economic and interesting features about which we should like to tell you, advise us you are interested and we shall.

MACHINE TOOL DIVISION

GREENFIELD TAP AND DIE CORPORATION
OF CANADA, LIMITED GALT, ONTARIO

If it's speed you need--

One trial will prove the advantage of Pratt & Whitney Milling Cutters. No matter what the nature of the work they will give you the highest production the machine is capable of.

They're designed for free, fast cutting. And tempered and seasoned to last longer.

PRATT & WHITNEY MILLING CUTTERS

Ask us for prices and details on Plain Milling Cutters, Side Milling Cutters, Inserted Blade End and Side Cutters, Screw Slot Cutters, Coarse Tooth Side or Plain Milling Cutters, Involute Gear Cutters, Concave, Convex and Double Angle Cutters, Cutters for Spiral Mills, Roll Thread Die Hobs, Key-Seating and Slotting Cutters, Straight and Spiral Cut End Mills (B. & S. and M. T. Shank), Spiral and Straight Shell End Mills, etc.

And we make formed cutters for special work also. All are backed by the guarantee for goodness that the P. & W. trademark indicates.

What is it that Causes A Belting to Become a Costly Burden?

Lack of quality—that is the answer. For when a belt commences to slip and waste power; when frequent breaks occur; when interruptions and holdups are daily happenings, that belt is **costing** you more than the price of a new one.

Eliminate all this once and for all by adopting D. K. McLAREN'S **Genuine British Oak Tanned** LEATHER BELTING—the long service belting that spells economy.

D. K. McLaren's belting gives long power-saving service because it is **quality** built. Consequently it is the most economical.

Every user is guaranteed of never-varying quality—because every belt is made from the world's best leather. Only the back portions of the choicest hides are used—tanned by the famous British Oak Tanning process.

For Economy use D. K. McLaren's Leather Belting

Look for the Oak Leaf ***The Sign of Oak Tanning***

SKINNER STEEL BODY INDEPENDENT CHUCK

Trade Mark

POWERFUL-STURDY-DEPENDABLE-ACCURATE

For production, where exceptional gripping power is required, where heavy cuts are often necessary and large pieces are held, this type of chuck will render most satisfactory service.

Although the Skinner Steel Body Chuck has been in use for years, we have never known of one breaking in service. It is the heaviest, strongest Independent chuck made.

Body—Cast Steel. Jaws—Extra wide. Adjusting screws—Large diameter.
Illustrated literature and catalogue on request.

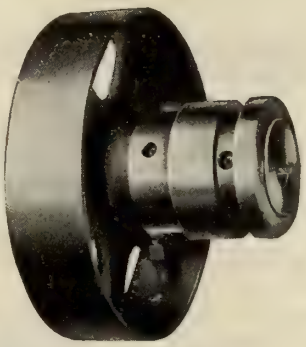
THE JOHNSON FRICTION CLUTCH

Friction Clutches From Stock



Johnson Clutches, both single and double, can now be obtained from stock in our standard slow speed type to fit all common shaft diameters and all standard pulley bores, within the range of light and medium horse powers that we cover.

State definitely —

Just what the clutch must drive.
Actual maximum horse power.
Speed of clutch shaft.
Diameter of shaft.
Diameter, width and bore of pulley.

We Will Select the Proper Clutch and Make Immediate Shipment on All Ordinary Requirements.

Friction Control Means Better Machinery

And the Johnson Clutch is supreme among friction clutches. Adopt it as your standard — always dependable and always promptly obtained.

Complete engineering service to consult on your problems and to handle special installations of any kind.

A Short Cut to Production

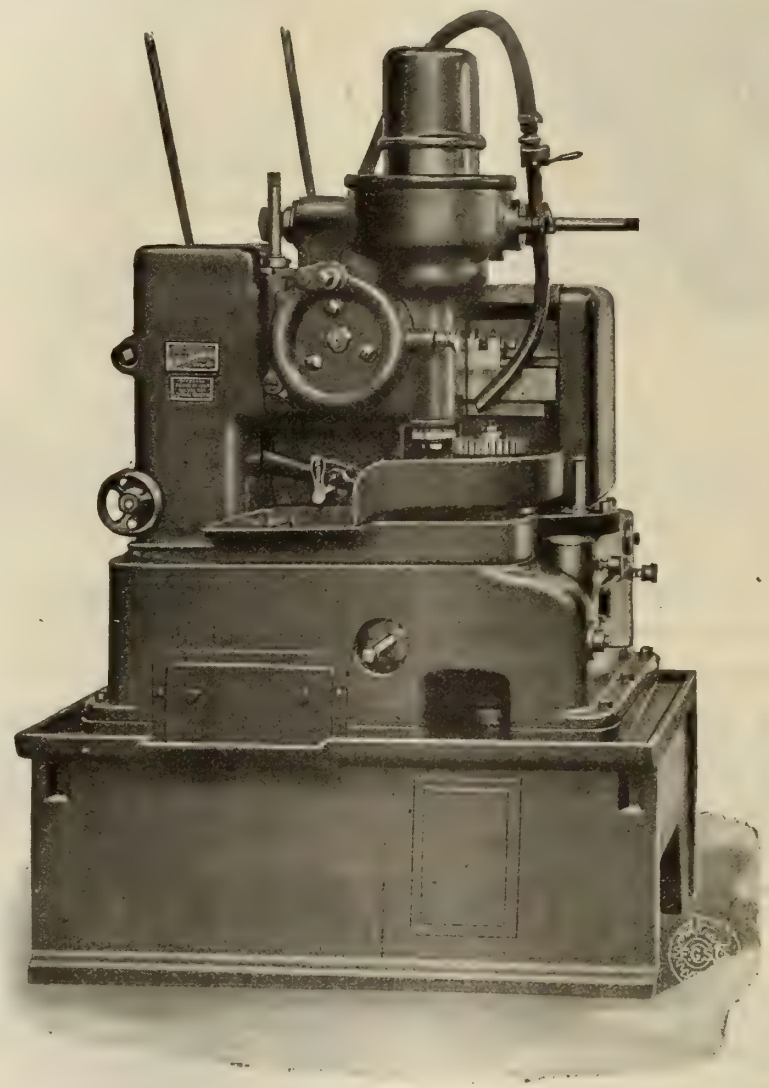
With the

"PROCUNIER"

SAFETY TAPPING ATTACHMENT

Tapping ½" open hearth steel couplings for a magnet drive with a 5/16" - 18" thread isn't exactly child's play, yet this sturdy youngster doesn't let it worry him any.

There are 16 holes in each piece and like all work of this class it must be accurate. With the "PROCUNIER" Safety Tapping Attachment, the boy shoves the work right along—one completed piece every 80 seconds, 720 holes per hour.



The "PROCUNIER" Safety Tapping Attachment reverses at twice its forward speed. Equipped with Safety Friction and balanced reversing mechanism that eliminates all torsion. Cut your costs with our Tapping Attachments, Safety Tapping Chucks and Tap Holders, which are all equipped with a patented "DOUBLE-JAW" Chuck. Ask for facts and figures.

WILLIAM L. PROCUNIER, 18 South Clinton Street, Chicago, Ill.

CUT GEAR COSTS
WITH THE
New Production Gear Shaper

The new production Gear Shaper, illustrated, has been designed to cut gear costs. It incorporates every feature necessary in a gear cutting machine to obtain this result, and still one of the outstanding features of the Gear Shaper principle—accuracy—has been maintained.
It is designed to cut one gear at a time and at a speed which eclipses all other methods.
All operating levers are at the front of the machine, permitting a number to be bolted together and operated as a unit, one 6 H.P. motor furnishing ample power for 10 machines.
It incorporates to the fullest extent the three principal requirements of production—high speed, accuracy and simplicity of operation.
See illustrated article in all technical magazines.
Send for our booklet, "A New Development in Gear Cutting," which has been prepared for the benefit of Engineers and Production Managers interested in the best gear cutting equipment available.

Write for your copy now.

HAMILTON, CANADA.

The Life Blood of the Factory

Dirty, gritty lubricating oil will junk your machinery long before its time. *Friction is production's worst enemy,* and the wear and tear caused by dirt and grit in oil slowly but surely wears out expensive bearings and other machinery parts.

Clean oil prolongs the life of machinery. Bowser Lubricating and Filtering Systems assure clean filtered oil on all bearings and restore the oil to its original lubricating quality. Try the Bowser Perfected Process of Seepage Filtration.

Installation takes a minimum of floor space.

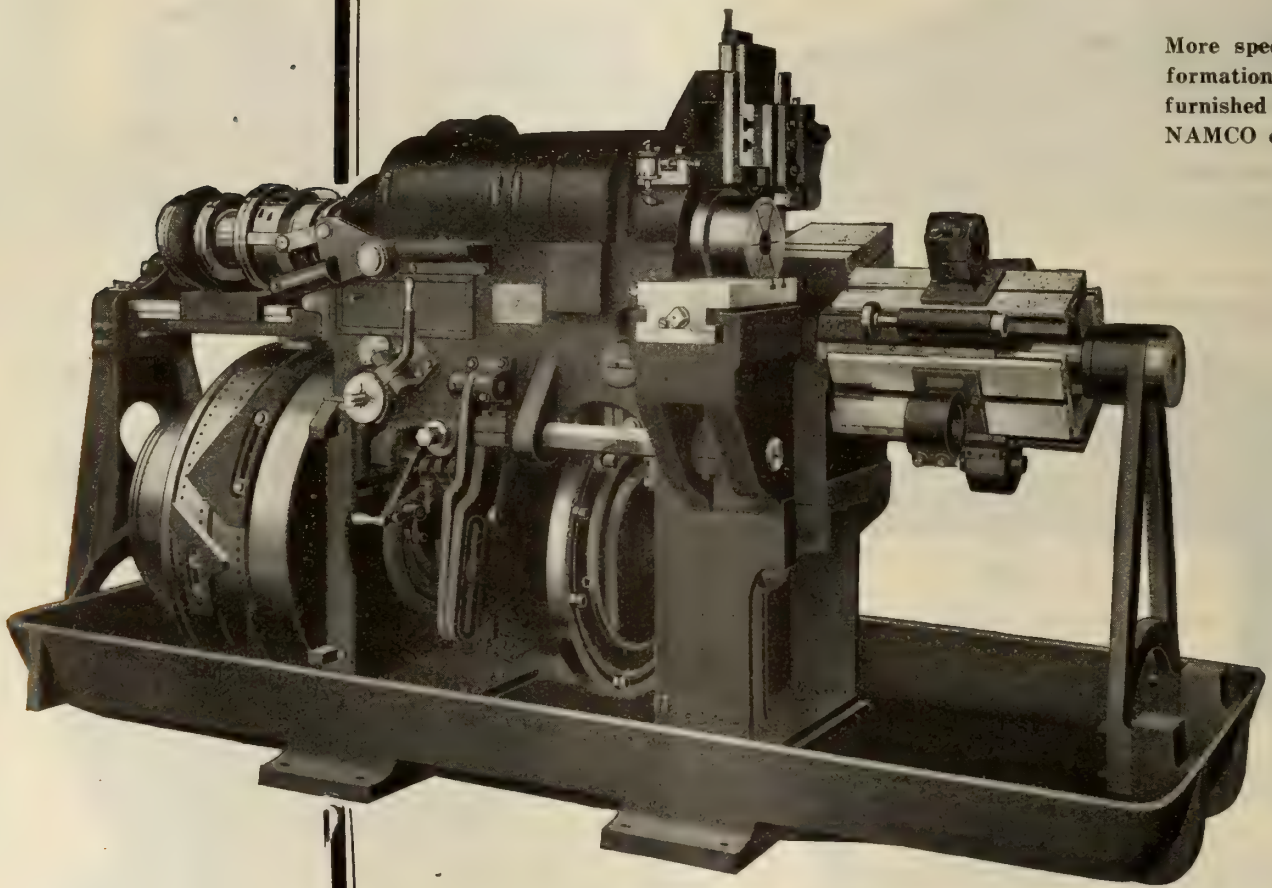
5¼"



Another New GRIDLEY

Now a part of the line of GRIDLEY SINGLE SPINDLE AUTOMATIC TURRET LATHES is this completely new automatic lathe.

Built with a capacity of 5¼ in. diameter this machine not only embodies well-known GRIDLEY principles but is also constructed to meet fully all the strict requirements for automatic forming, drilling, boring and turning of such heavy bar stock.

The new features include single belt drive, mechanically positive feeding of stock, gear transmission with automatic shifts, improved cross-slides, new top slide, new indexing mechanism and spindle bearings, and full support of stock and tool slides.

Link-Belt Equipment for Cutting Handling Costs

THE cost of handling materials is an important factor in maintaining low production costs.

Thru many years of experience we have developed machinery that will handle raw or finished products economically, and which require little attention or labor, operating almost automatically.

The above are a few typical illustrations of Link-Belt machinery.

To find out whether there is a more economical way of handling your material, talk the matter over with our experienced engineers.

Monel metal measures power plant efficiency

DEVICES depended upon to detect and "show up" inefficient power plant operation can do their work no better than each metal part in them.

Coal, hot flue gases, steaming boiler feed water, high pressure and superheated steam, all act to wear out the device used to measure, handle or control them.

Metals commonly used for contact parts in these devices yield to corrosion—rust out. Of the commercial metals, only Monel combines the strength of steel with the ability to stand up under the attacks of most acids and alkalies and of high heats and high speed vapor erosion. Therefore, vital parts of automatic coal-weighing scales, CO_2 Recorders, Venturi meters, flow meters, hot water meters, gauges, etc., are made of Monel.

In addition to the few uses for Monel listed above, leading designers specify Monel. Monel is now used in many places where other metals have been tried and have failed. For instance, Chapman, Crane, Jenkins, Lunkenheimer, Nelson, Pratt & Cady use Monel for valve stems, seats, rings, clappers, spindles, etc. It has a prominent place in the specifications of the largest engineering organizations in the country.

THE INTERNATIONAL NICKEL COMPANY OF CANADA, LIMITED

Greater
Production
-Less Cost
MEZZO

Greater Production ~Less Cost

The cry of the present day is Greater Production—but lower cost.

We have realized that a large number of shops are not properly equipped to obtain the most economical production from either high speed or carbon drills.

High Speed drills require great speed, and rigid machinery, factors which are lacking in a great number of plants.

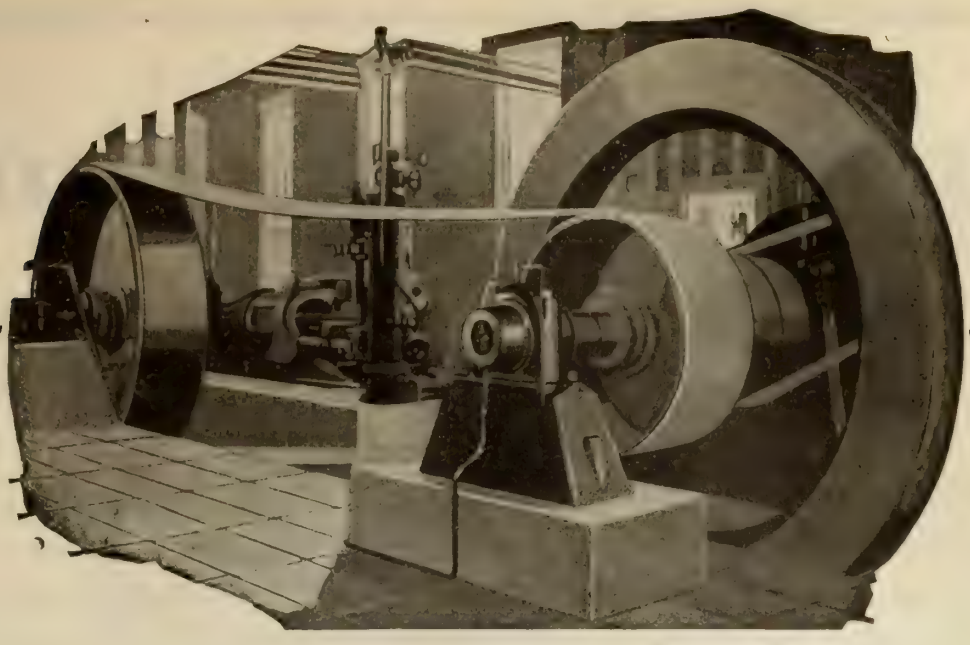
Carbon Drills do not give these plants sufficient production.

To meet this demand, we have perfected a new drill.

MEZZO

We firmly believe that "MEZZO" is the greatest advance in drill manufacture in the last twenty years.

"MEZZO" performs best at speeds and feeds which would soon burn the point of a carbon drill. In fact we recommend that "MEZZO" be used at approximately double the feeds and speeds at which carbon drills under average conditions work satisfactorily. At these speeds and feeds "MEZZO'S" durability and production have astonished many of the wiser heads in the cutting tool field.



Heating the cutting edge of "MEZZO" even to a dark blue color will not draw its temper. In fact "MEZZO" works at its best efficiency this way.

And "MEZZO" is reasonably priced; gives greater production—reduces production costs.

Write for the *"Story of Mezzo."* It will tell you how you can obtain this greater production at less cost—right in your own plant.

WHAT DO YOU LOOK FOR IN A BELT?

Dependability

Dominion Friction Surface Belting assures trouble-free service. Once adjusted you simply forget it. It runs absolutely true, pulls evenly without slippage and consequent loss of valuable power. The extreme flexibility, toughness and pulley-hugging qualities guarantee perfect transmission even under varying conditions of temperature and load.

Endurance

Dominion Friction Surface Belting assures consistent operation. Made of several uniform lengths of heavily impregnated plies, all securely cemented together under extreme pressure, it is built for sincere service—and gives it.

Cost

Dominion Friction Surface Belting is by far the most economical, even in purchase price. Many plants throughout Canada have demonstrated to their satisfaction the many distinct money-saving and power-conserving features of Dominion Friction Surface Belting.

Our engineers are at your disposal—their recommendations obligate you in no way whatever. Write our nearest service branch about your belting problems.

Now is the Time for Repairs

Many a Factory and Mill can confidently look forward to an early date when their plant will be running full time. Every factory should be gone over and needed repairs to BELTING attended to now. It would be disastrous to stop at a rush time and it would be foolish to run the risk of a hold-up through neglect.

Look Over the Belting

To make sure your wheels will never stop turning through the breakdown of Belts, equip every machine with

ANNOUNCING

The New Landis 12" Pipe Threading and Cutting Machine

WITH QUICK POWER TRAVERSE

Insistent demand by pipe machine users who know, has brought forth this new member to the well known family of Landis Pipe Threading and Cutting Machines—a demand for a machine rigid and powerful enough to afford the proper support for the high speed Landis Die Head and Chasers.

This new Landis embodies the latest in machine tool design and makes enviable progress in the threading and cutting of pipe and oil well casing efficiently and economically. Some of the most important points are:

1. Power traverse for carriage.
2. Double lever friction clutch for starting and stopping machine.
3. Reversing feature for flange work.
4. Reaming tool locked, eliminating human effort when reaming.
5. Single pulley drive and eight (8) rotative speeds for pipe.
6. Gear box is in one unit and is mounted on ways of machine under main spindle.
7. Quick convertible feature for motor drive.
8. All gears in gear box run in oil bath. Spindle bearings are lubricated by flat link chain running in oil.
9. Weight 13,000 pounds.
10. Landis Die Heads and Chasers employed.

May we send you leaflet giving details?

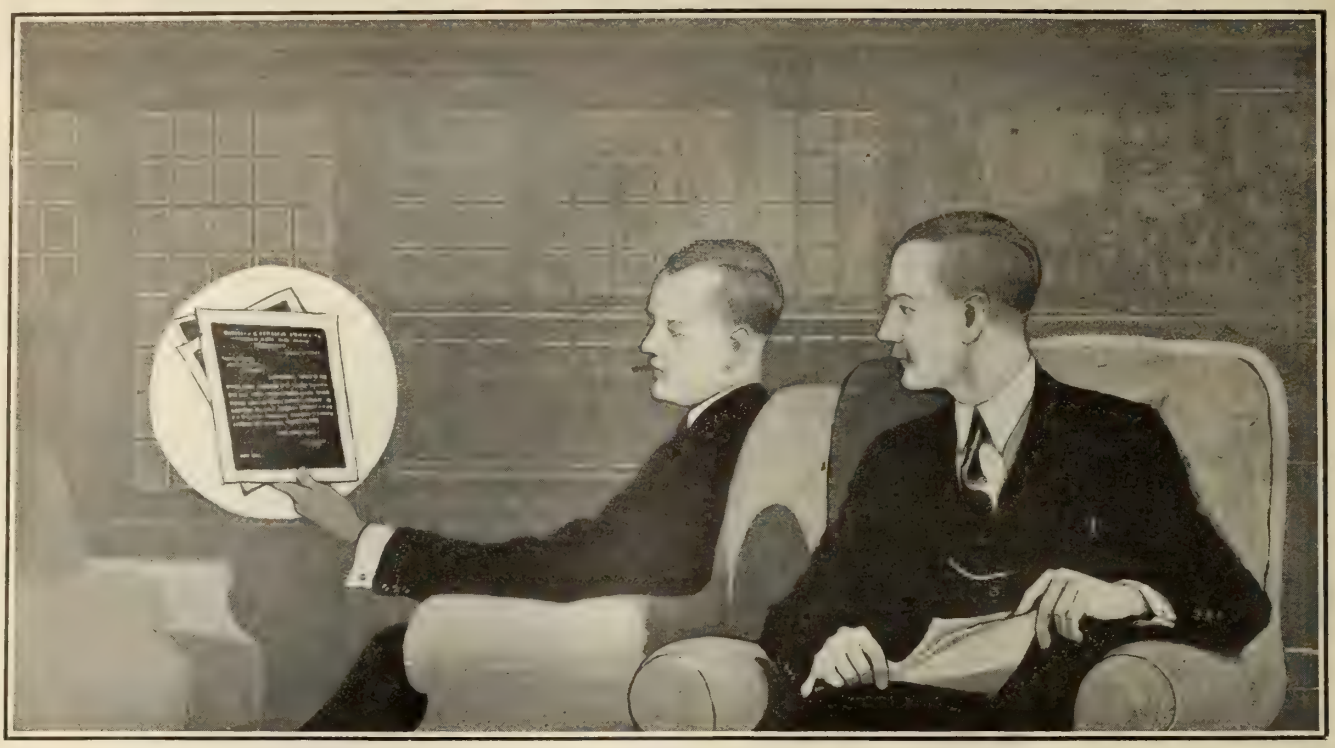
If You Can Use A Welding Torch You Can Make Your Own Couples



If you can weld two pieces of wire together at one end, you can make your own thermo couples for Hoskins Pyrometers. One of these wires is Chromel, while the other is Alumel. These alloys are used in the majority of pyrometer installations, not just because the man can make his own thermo couples from them, but because they have proved to be the best base metal alloys ever developed.

A pyrometer installation for which the user can make his own thermo couples without calibration is cheaper to maintain. The low first cost of Chromel couples, their long life, and their low maintenance cost makes them very economical. Their accuracy makes them absolutely reliable.

Hoskins Pyrometer and Couples are described in Catalogue 31R. Send for it today.

"Real Sales Helps—PHOTOSTAT Prints"

With a PHOTOSTAT you can send your salesmen and agents facsimile copies of testimonial letters. You can send these on the same day they are received and in a size that will fit the salesmen's books. You can also send them copies of rush bulletins, clippings, catalog pages, explanations of new designs, laboratory reports, and other sales helps.

You can get these copies to the salesmen while the material is real news, because it only takes a few minutes to make a PHOTOSTAT print. Your salesmen will appreciate such co-operation.

In addition to furnishing sales helps quickly and at small cost, the PHOTOSTAT also has great value for the production department in making photographic facsimiles of pencil sketches, drawings, blue prints and even of small articles. Here the PHOTOSTAT eliminates the necessity of making tracings. The PHOTOSTAT copies directly on sensitized paper at original, enlarged or reduced size.

In the office the PHOTOSTAT eliminates the mechanical drudgery of copying by typewriter or longhand. It copies letters, telegrams, reports, graphs, charts, shipping lists, contracts, ledger pages, insurance records, legal documents. These PHOTOSTAT copies do not have to be read back for errors or checked with the original. You **know** they are right.

Just ask for a copy of our booklet, "The PHOTOSTAT and What It Will Do."

Centralized Repair Shops Are Bull's Eyes For Regrinding

IF YOU are connected with automobile repair work in any manner, such as a small machine shop, welding concern or even a regular garage, you are passing up an excellent opportunity if you do not look into the regrinding of automobile cylinders. Especially is this true if you are located in the center of a large number of registered cars, not necessarily in the city but a strategic point in a medium sized town.

It is a new proposition to both repairmen and motor owners but its results are fast becoming known to both and the latter are, in a large percentage of cases, insisting on reground cylinders when overhauling to enable them to get a motor as good as new.

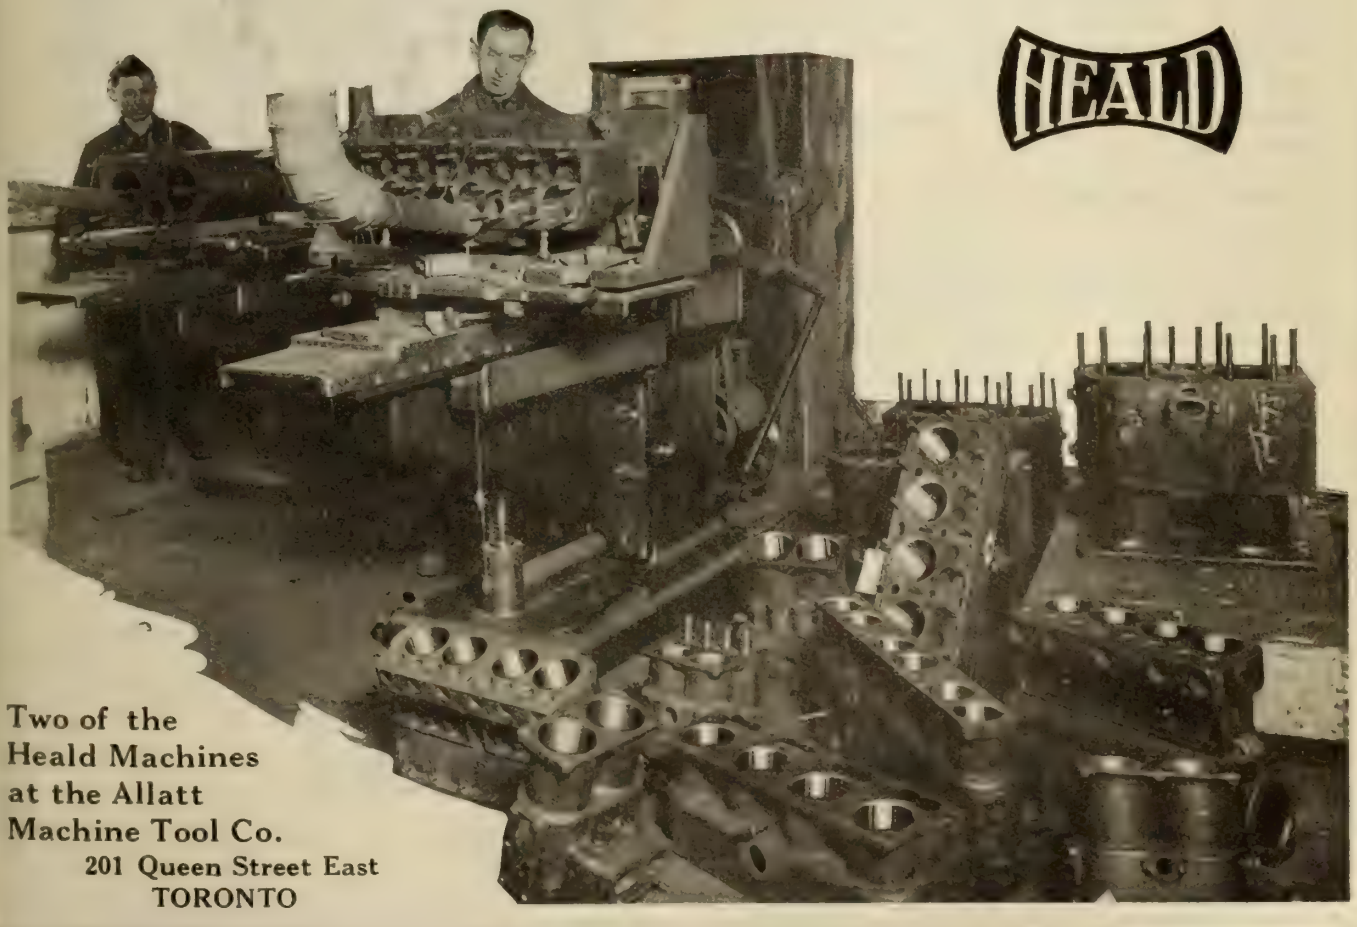
The commission usually allowed to garages is sufficient to make it a worth while proposition for them, especially when they are not in a position to put in the necessary equipment, and by obtaining work from all of these in your working center, you will get unusually handsome returns on the investment.

Once established you will create a market that now does not exist for there are many owners who do not know of the value of a reground block and still more who do know but neglect having it done owing to the inconvenience of sending the block away.

The Heald Style No. 55 was built especially for this class of work, simple, reasonably priced and with a range that will take care of any block that you may have, whether it is from a pleasure car, truck, tractor, motorcycle or marine engine.

Heald machines are used exclusively by every motor manufacturer that grinds his bores and motor owners who fully appreciate a reground job will insist on having it done on a Heald machine.

We would be glad to talk over the possibilities personally with you, giving you our frank opinion and furnishing you with sufficient information that will enable you to decide for yourself whether you can make a success of it or not.



Get in touch with us direct or through our branches or agents.

MACHINE SCREWS

How Much Does an Hour's Delay Cost You?

What are your hour costs? For convenience, say they are based on 4 cents a minute per man—$2.40 an hour. Consider the amount of time lost, and the unnecessary expense that is incurred, when your men are held up in course of assembling a machine **through badly fitting screws.**

It pays to carefully choose your machine screws.

Torrington products can be thoroughly depended upon. Every Torrington Machine screw makes a true fit. It is because of this attribute, coupled with strength, that Torrington products have won the confidence of discriminating buyers. If you are not a user of Torrington products why not at least give them a trial.

The Torrington line consists of standard and special machine screws, rivets, threaded wires and specialties in headed work.

KAELIN ELECTRIC STEAM GENERATORS

Their Field

Any mill or factory developing its own power which has surplus electric energy during the whole or any considerable part of the day.

Any mill or factory operating on bought power purchased on a "flat rate" basis; but which is not using all the power allotted to it.

Capacities

These Electric Steam Generators are built in sizes from 600 to 25,000 K.W., corresponding approximately to 60 to 2,500 Boiler horsepower.

They can be operated by alternating current only, and are built for voltages varying from 550 to 12,000.

Advantages

Their first cost including installation is low compared with any type of coal or oil-fired boiler plant.

They are safe, clean, easily regulated, require but little attendance and take up very small floor space.

They can be operated in parallel with existing boilers or can be installed close to their work.

Information and prices promptly submitted on receipt of particulars as to your conditions.

Needles and Locomotives

NEEDLES and locomotives and no doubt your own product—all have to be cleaned. All are different. Yet on all, modern methods of cleaning mean saving time, labor and money. The experience of many manufacturers in a wide range of industries has proved it time and time again.

For instance: A Western needle company formerly used gasoline for cleaning needles before plating. Now uses Oakite because in addition to perfect cleaning results, there is a direct saving in labor of $1,650 a year, and a saving in the cost of cleaning materials of $250 a year, making a total annual saving of $1,900!

Another instance: A railroad shop in the East discontinued the use of a strong lye solution for removing oil, grease and dirt from locomotive parts; and uses Oakite materials instead, because the average cleaning job which formerly took 5 hours has been cut to a half hour!

These are bare results—the "answer" to two widely different cleaning problems. But in seeking the solution of such problems, it is not merely the matter of substituting a better cleaning material for a less efficient one. It is instead, a matter for careful study, proper analysis and exhaustive test. It is also a matter of the application of complete and exact knowledge gained through the experience of many years in improving cleaning conditions. And finally, it is a matter of making definite recommendations as to cleaning *methods* as well as cleaning materials.

These are the factors that make up OAKITE SERVICE. And it is this service that we offer freely without charge or obligation, to all manufacturers, especially those—

(1) Who are getting unsatisfactory cleaning results.
(2) Who know that their cleaning work can be improved.
(3) Who are satisfied with their cleaning work but wish to make certain that their methods and materials are giving most economical results.

Put YOUR cleaning problem up to us. Ask us to send a SERVICE MAN. It may result in an important saving to you. A call implies no obligation on your part.

Precision Instruments Will Improve Product

Passing of the Vulgar Fraction in Shop Practice—Standardization Only Possible Through Precision Tools—Measuring to a Millionth of an Inch—Application of Gauge Blocks.

By H. A. WILSON

THE USE of precision instruments in machine shops and manufacturing industries has become more or less a matter of course, with the result we find many examples of delicate measuring instruments in industry to-day. Very few people, even among those whose daily duties take them into the machine shops of our country, realize just what a tremendous part precision instruments have played in modern manufacturing methods. The present state of civilization calls for quantity production in a multitude of ways, and were it not for precision instruments, quantity production could not have been developed. Standardization has given us at a reasonable cost, a large proportion of articles we use in our daily duties and pleasures. Many of these are considered as necessities at the present time.

Measuring by Caliper

Before the advent of the micrometer, one of the commonest of precision measuring instruments, the caliper, was the one universally used in machine shops. With this tool, measurements smaller than 1/64 of an inch were rarely used. With the micrometer, the decimal system replaced the only method of using fractions. Thus, the inch was divided into a thousand parts. It was not long until micrometers were manufactured that accurately measured to within one ten thousandth part of an inch. Such instruments are now in daily use.

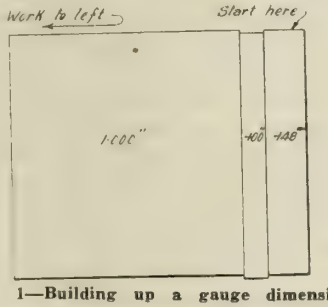

Fig. 1—Building up a gauge dimension.

Modern machine shop methods, in dealing with the shaping of metals to conform with the ideas of the designer, as expressed by blue-prints, involve a great number of measurements in order that component parts of an article will fit in a manner that will permit them to function properly. Thus, the very success of a machine shop depends on measurements. It is claimed that all important discoveries have been made through the medium of fine measurement. In the measurement of time, mass, and length, the latter mentioned is the most difficult, and it is in the precise measurement of length that exists the very centre of control in modern machine production. With the development and growth of the machine industry, the necessity of accuracy in measurement has become more and more important, until to-day the establishment and maintenance of sizes in both tools and product is one of the great problems before the machine shop world.

Evolving Modern Methods

In the days of the caliper the men who worked in machine shops were "all-round" machinists, that is to say they were experts in the operation of the various standard machine tools, as well as in bench work and assembling. Factories were also "all-round" shops, which produced complete machines, not one or more parts of some machine. To-day conditions have changed, and we find the "all-round" man has given way to

Fig. 2—Checking location of holes in drill jig.

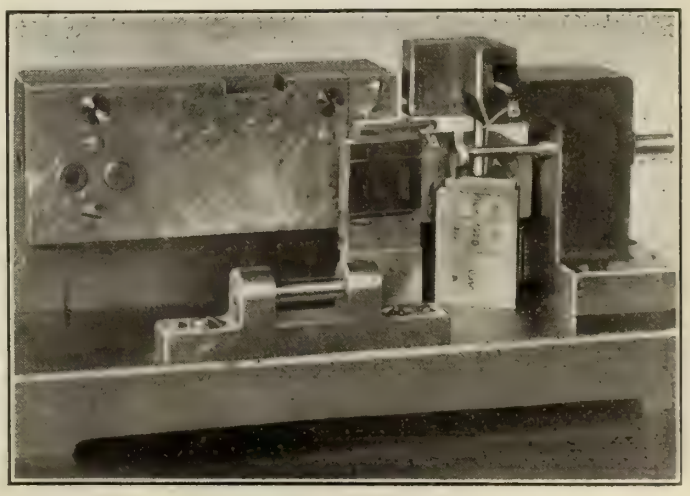

Fig. 3—Checking accuracy of special gauge.

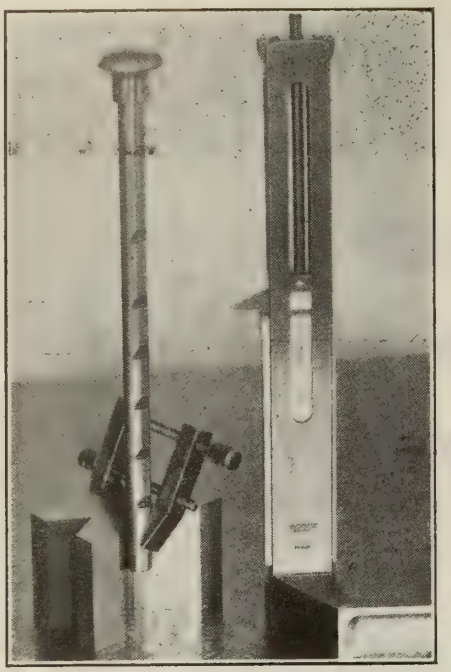

Fig. 4—Testing notches in measuring rod with height gauge.

the highly specialized operator. It is quite within the realms of possibility that in shops which employ a large number of workmen, there might not be more than a dozen or so "all-round" men outside of the tool-room or experimental department.

No one doubts the fact that these modern methods are with us permanently. The fact that the practices have decreased manufacturing costs and have greatly increased both the quantity and quality of the work produced, is sufficient reason for their general adoption. Under the old order of things the securing of a proper fit between mating parts was made by the "cut and try" method, which is simplicity itself, but slow and expensive, both as to original manufacture and subsequent upkeep. Moreover, the very system itself was such that errors in workmanship could be corrected. That is to say if a workman turned a shaft a bit under size he corrected his error when he came to bore the hole into which the shaft fitted. But with modern methods impregnating the entire industry, the opportunity to correct variations from standard sizes is gone. Under these modern conditions the workman in one department may never see the workman in another department, and neither of them may ever see the assembled product, as they continue to devote their entire efforts to the machining of a component part. Obviously each part produced in a shop under this manufacturing system, known as quantity or interchangeable production, must be true to the blue print, so that component parts selected at random from the stock accumulation of various departments will assemble with the minimum expense of time and effort.

The principles involved in interchangeable manufacture, have been applied also in a broader field than that of the departmentalization of shops. The production of various parts of a given machine is often accomplished in entirely different shops located hundreds miles apart, and all these component parts are shipped to one place where they are assembled. The problem of having pieces machined to close limits at a dozen different places in the country, and then shipping same to some central point where they are inspected and later assembled without undue difficulty, is one of the highest industrial importance, and one which has been solved by the successful application of precision measuring.

To accomplish this engineering feat two things are necessary, first, the departments of the single shop, and the departments of different shops must be in accord, and know beyond the possibility of a dispute just precisely what constitutes an inch or any fractional part of an inch; and second, these departments and shops must not only know what an inch is, but they must also use measuring tools which permit them to work in inches and fractions with the least possibility of error. Any measuring tool that makes possible such uniformity:—

(1) Must give both external and internal measurements in the ten thousandth part of an inch.

(2) Must give the same result any number of times.

(3) Must give the same result in the hands of different mechanics.

(4) Must be capable of being used direct on the work, so that the possibility of error, due to transferring fine measurements, is eliminated.

(5) Must be so seasoned that the well known changes taking place in hardened steel are reduced to a point where they do not impair the accuracy.

(6) Must be self checking, so that error due to wear becomes known at once.

Developments of Gauges and Standards

After reading the foregoing one sees that the practical shop application of the science of precision measuring is to develop a system of gauges, standards, gauge blocks, master gauges, etc. Experience has shown this method to be among the best, and with the assumption that this statement is correct a few illustrations on the use of gauges, gauge blocks, and standards will be shown.

A gauge block is a piece of hardened steel that has to conform to a stiff set of specifications, some of which are that it must be accurate to almost perfection, say to the one hundred thousandth part of an inch, it must be flat, its sides must be parallel, it must be thoroughly seasoned so that it is only slightly affected by temperature changes, and if affected it must expand and contract uniformly. It must return to size when it is again brought to normal temperature, and many other more or less important conditions. Simple as these rectangular blocks of steel are, their possibilities in the hands of a mechanic are only limited by his experience and resourcefulness. A number of blocks are often combined to obtain a measurement equal to the sum of the combined blocks. No inaccuracy results from this practice and this method is very useful in checking one block against another, or even a series of blocks. It will be found, that the surfaces of such blocks are so accurate, that they will adhere to each other, thus allowing the mechanic to use them in the same manner as a solid gauge if necessary. When blocks are combined

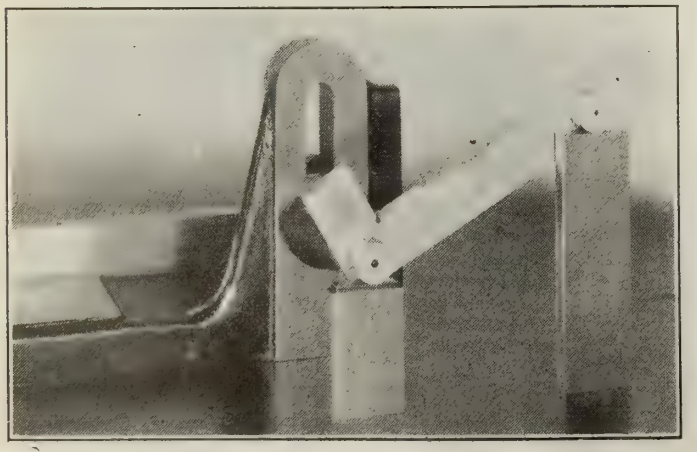

Fig. 5—Setting sine bar by use of blocks.

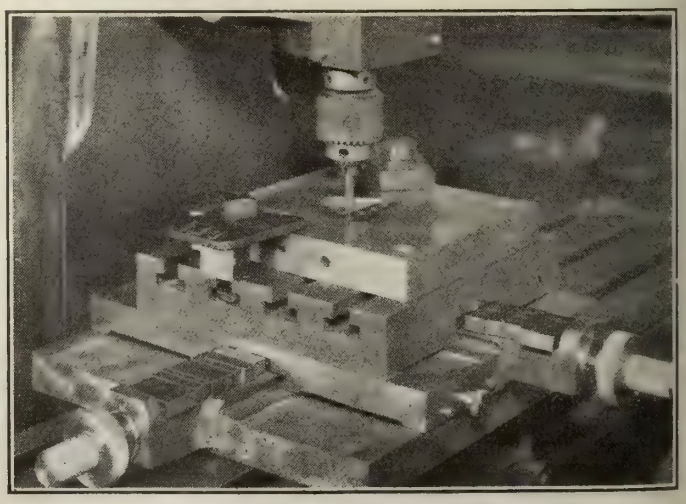

Fig. 7—Accurate spacing of holes by means of gauge blocks.

to get a certain measurement, a little care is necessary to save time and get best results.

In building up blocks the first point to study is the elimination of the extreme right hand figure, for example, suppose we desire to build up to 1.248 in. Looking over the blocks we pick out as shown in Fig. 1, a block .148 in. thick. This gets rid of, as mentioned above, the extreme right hand figure. We next secure a block .100 in. and another 1.000 in. which we assemble together, this making 1.248 in. total. In all cases endeavor to work from right to left using the smallest possible number of blocks to obtain the desired number of blocks.

Gauge blocks are valuable as reference standards for establishing and maintaining important dimensions. To a great extent master gauges can be eliminated, and as the blocks are not of special design they can be used over and over again on various jobs and do not become obsolete. These types of blocks are generally used on layout work, building and checking, inspection, and working gauges, as well as dies, jigs, fixtures and tools. A few accessories are manufactured and marketed with these precision blocks which expand their field of usefulness.

Practical Use of Gauge Blocks

Fig. 2 shows gauge blocks used directly to check the location of holes in a drill jig. The cut tells its own story and is a good example of the use of gauge blocks for precision measuring.

Fig. 3 shows another example of precision measuring with gauge blocks. Here is shown a special gauge being checked for accuracy. Fig. 4 shows the accessory clamp and base used in connection with the gauge blocks in the capacity of a precision height gauge. The particular job shown is the checking of the notch spacing on a measuring rod. Fig. 5 shows the gauge block method of setting a sine bar, while Fig. 6 shows

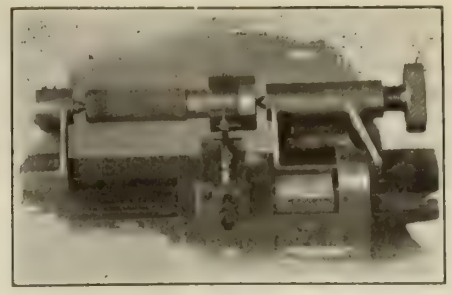

Fig. 8—Testing lead of thread by use of gauge blocks.

the use of blocks to locate holes in work on the face plate. Fig. 7 shows the blocks used to space holes in die work, while Fig. 8 depicts the blocks in use as a part of a thread-lead testing machine. All these examples are self explanatory and each contains many interesting features for anyone anxious to study the field of application of these precision measuring blocks. The above are only a few of the manifold applications.

Fig. 9 is another interesting and rather unique application of gauge blocks in the gauging of steel balls. The two plates are spaced by gauge blocks, being a little closer at the top than at the bottom. The balls roll down the plates, dropping into chutes after they pass through the proper spacing. The balls are placed in the hopper at top, and as the base revolves, balls from the hopper are discharged at proper intervals into the troughs, and in these troughs they are not only gauged but sorted. The edges of the plates that do the gauging are ground to a knife edge, and these need constant attention and are usually re-ground after approximately twenty thousand balls have been gauged. There are from four to six pairs of plates on each of these machines.

Absolute Measurements Impossible

Sooner or later a mechanical man comes up against the fact that absolute precision is an ideal not possible of attainment in the sphere of mechanical operations. Furthermore there are a variety of fits in even the most simple machine. Fig. 10 shows how many fits are required in the simple little drill press and each measurement has a certain variation in size which is permissible, this being defined by two dimensions. Such work as this must also be gauged, both instruments such as micrometers, and gauge blocks would not be suitable to this work as speed is required and is quite as essential as accurate results. Thus a new method of precision gauging had to be evolved.

In all production shops it has been found that it is not desirable to supply operators with micrometers, as these tools are expensive, and at the same time if used constantly, wear sooner or later, with results which render the instrument readings inaccurate. Even with the best of care the errors due to wear will creep in. But such tools do not always receive the best of care, thus the micrometer is usually only found in the tool room and experimental departments. In most parts, even when machined to so-called fine measurements, a limit of a few thousandths, or ten thousandths is essential. For that reason snap gauges have replaced the micrometer in some cases. There are several reasons for this, which are more or less obvious. Snap gauges are comparatively cheap as compared to micrometers or

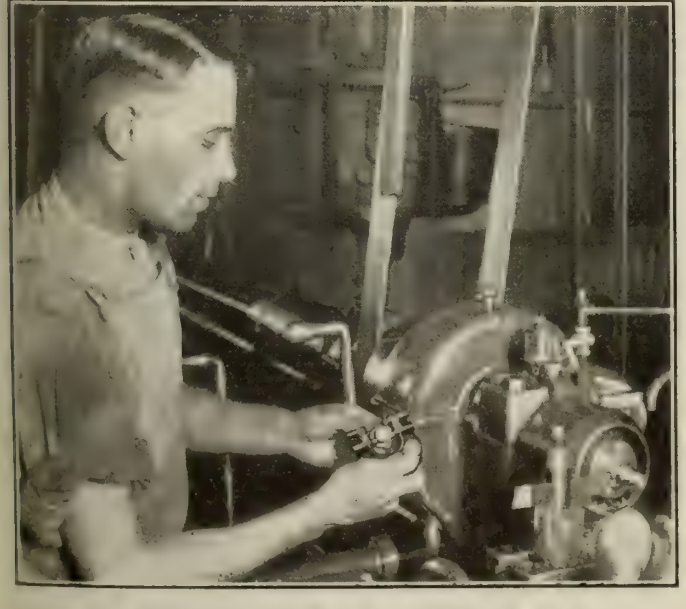

Fig. 12—Gauging work with adjustable snap gauge.

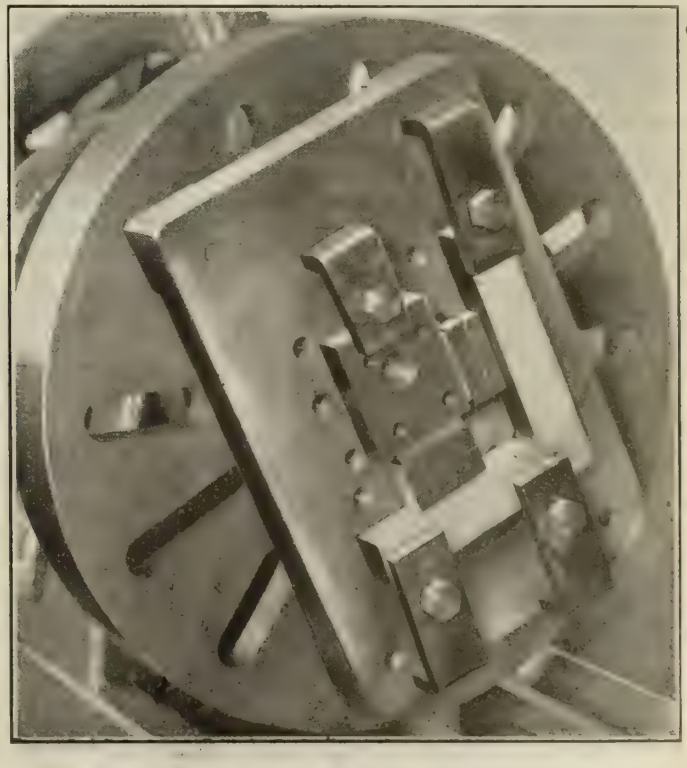

Fig. 6—Application of blocks in locating holes on faceplate work.

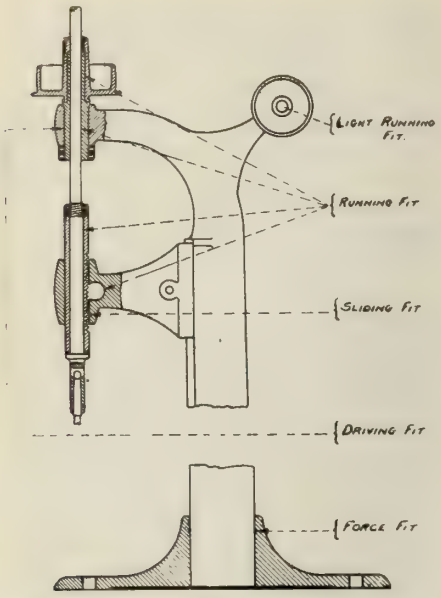

Fig. 10—Different fits required in drill press construction.

other precision instruments. They are usually rugged and can stand a great deal of hard usage, that would be termed abuse to a more delicate instrument. Snap gauges can be made adjustable over a fair range of limiting dimensions. Worn anvils can be replaced. A high and low limiting set of anvils can be placed in one holder which saves a great deal of time in gauging. All these reasons have made the snap gauge a popular type of gauge for handling precision work. It is the system of machining work limits that created the demand for a limit snap gauge. Drawings are usually marked with certain dimensions, plus or minus, between which limits it is necessary to keep, in order that the work may be suitable. Care, and practical shop experience, are desirable in placing limit dimensions on drawings. It is very easy to specify too close limits and waste money, or to go to the other extreme and specify too wide limits and miss the result sought. Many variable quantities enter into the problem of determining these limits, but it must never be lost sight of that production hinges upon the equation, (as one might term it)—closeness of fit versus cost. The closer the limits, the greater the costs, therefore for commercial purposes we should find out just how inaccurate work can be machined and still be suitable for its purpose, then make the limits as wide as possible.

Interchangeability is sometimes confused with precision manufacturing. Precision manufacturing usually means interchangeability, but interchangeability does not always mean precision work. Take for example the cast iron stove lid. It is surely interchangeable but cannot be thought of as representing close limits. In discussing the range of limits, the nature of the product must be considered. The diameter of a large pulley can have a wider range of limits than the diameter of a gas engine crank shaft.

Now it has been shown that limits are necessary to the commercial success of manufacturing, and that these limits vary with different classes of product. It is not wise to leave to the judgment or skill of the individual operator the final decision as to the amount of variation from the nominal dimension that will be tolerated. Therein lies anot reason for the snap gauge, which is an instrument of fixed dimensions thus being largely free from errors due to the human factor.

Gauge Construction

The general appearance and design of a snap gauge is well known to all who have even a bowing acquaintance with shop practice. The details of construction which permit of the adjustable features, however, are not so well known. Fig 11 shows a cross section of one end of an adjustable limit snap gauge. There is also shown the construction of the thumb and finger insulated grip, which feature prevents the heat of the hand from expanding the gauge. The cast iron frame gives rigidity with lightness. The Swedish cast iron is not liable to distortion as it will not bend, warp or spring under any normal, and many abnormal, conditions of use. The gauging plugs or anvils have a flat side which prevents rotation and only permits of end motion. These anvils are bevelled so that they slide on the work easily without marring it. The bevel is always in the correct position as there is no rotation of the gauging plug. The two adjusting screws are headless set screws. The clamping screws hold the gauging plugs firmly in place. The adjusting screws can be sealed with wax to prevent tampering after the gauge has been set. This type of gauge when set, can be depended upon to give excellent service in precision gauging. It is really fool proof and gives the same result in the hands of any operator, mechanic, or inspector. The gauges can, of course, be set with standard gauge blocks.

Fig. 12 shows the application of the adjustable limit snap gauge in checking work as it comes from the machine. Errors are thus detected at the outset before a large number of pieces are spoiled. The plug gauge is no less important in the shop than the snap gauge. The former takes care of external dimensions while the latter is used on internal dimensions. Usually there are two plugs, the low limit or "go" end, and the high limit or "no go" end, located on a central handle. Thread gauges are usually of the same design but these as well as plug gauges, will be discussed later.

PROTECTING IRON FROM RUST

Protection of iron from rust or oxidation is a matter of more than ordinary concern. It has been tinned, painted in oils and coated with tar and varnish, with the intention of preventing weather influences operating upon it. Whilst the three latter methods are unquestionably economical in first cost, says a writer in the Practical Engineer, they but imperfectly serve their purpose, whereas the protection by means of coating with zinc, or galvanizing, unites together the requisites of perfect protection at a comparative minimum of cost. Zinc is preferable to lead, as chemical experiments have demonstrated that while it effectually protects, it is not operated upon by water in the same manner as lead.

How Executives Can Show A Steady Profit

Fear of Failure Must Not Be Entertained—Put Service Before Profit—A Well Conducted Business Will Show on Right Side of Ledger—Standardization Alone Will Not Bring Business.

EVERY executive is interested in making a profit, especially at the present time. Henry Ford believes in making a steady profit, and here are a few of the things he claims are responsible for his firm's past achievements.

"It used to be taken for granted," says Mr. Ford, "that our theories and methods were fundamentally unsound. Events have killed that kind of comment, but there remains a wholly sincere belief that what our company has done could not be done by any other company, that we have been touched by a wand, that neither we nor anyone else could make shoes, or hats, or sewing machines, or watches, or typewriters, or any other necessity after the manner in which we make automobiles and tractors. And that if only we ventured into other fields we should right quickly discover our errors.

"I do not agree with any of this. Nothing has come to us out of the air. We have nothing that others might not have. We have had no good fortune except that which always attends anyone who puts his best into his work. There was nothing that could be called 'favorable' about our beginning. We began with almost nothing. What we have, we earned; we earned it by unremitting labor and faith in a principle.

"The institution we have erected, differs as a whole, although not in every respect, from all other businesses that I know of. It differs because we made it differently. If we had not done so it would not be there. It is founded on essentially this creed:

"1. An absence of unreasoning fear of the future or veneration for the past. One who fears the future, who without reason fears failure, limits his activities. Failure is only the opportunity more intelligently to begin again. There is no disgrace in honest failure; there is disgrace in fearing to fail. What is past is useful only as it suggests ways and means for progress.

"2. A disregard of competition. Whoever does a thing best ought to be the one to do it. It is criminal to try to get business away from another man—criminal because one is then trying to lower for personal gain the condition of one's fellow men, to rule by force instead of by intelligence.

"3. The putting of service before profit. Without a profit, business cannot extend. There is nothing inherently wrong about making a profit. Well-conducted business enterprise cannot fail to return a profit, but profit must and inevitably will come as a reward for good service. It cannot be the basis—it must be the result of service.

"4. Manufacturing is not buying low and selling high. It is the process of buying materials fairly and, with the smallest possible addition of cost, transforming those materials into a consumable product and giving it to the consumer. Gambling, speculating and sharp dealing tend only to clog this progression.

"These principles have been put into effect by a process which is very loosely called 'standardization'—as though the program called for machines rather than for principles. Standardization and simplification—all the terms that gather 'round them—mean nothing of themselves. One must first get at the motives.

"Standardization? Standardization for what? To make a higher profit on each article sold? That kind of standardization inevitably results in failure. If I were making and selling a shoe at $5 at a profit, under wasteful methods, I could undoubtedly by accepting that shoe as a standard and arranging my manufacturing processes accordingly, make a much higher profit on that shoe's sale at $5.

"That is the way most standardization goes. A manufacturer turns out, let us say, a dozen styles of articles. He decides to standardize his processes of manufacture. He cuts the dozen articles to three. Inevitably he cuts his costs and he finds for a while that he is making more money on the three articles than he did before on the twelve. He has not cut the price to the consumer. He has not been thinking of the consumer, excepting as someone who will give him money.

"Before long he finds his sales falling off. His distributors report that they are overstocked and they begin to ask for new styles. Eventually the manufacturer finds that he differs from his former condition only in that instead of having a poor business in a dozen articles he has now a poor business in three articles. Standardization alone will not bring business.

"The place to start standardization for volume output (and no other kind of standardization is of any consequence) is with the consumer. One must work back from the consumer, and the points to decide are: 1. Am I able to make what the people want—make it better than anyone else? What price can the consumer afford to pay? Can I trust myself to remain faithful to my principles?

"This is not illogical; it is simply keeping in mind that the consumer is going to control the business and you therefore accept his control first instead of last. The public wants a definite number of things. I spent 12 years, day and night at the drawing board and in the shop before I knew that I could make something which the people would want.

"The price of our products has ever been made on what it ought to cost to manufacture that product. We have always taken the price and worked back. Every price has been a challenge to ourselves. It has always been below the lowest cost we could figure out in advance. Then we have gone ahead with that price hanging over us and found so many new, better and less expensive ways of doing things that the price which once, under the ordinary method of calculation, would have been considered impossible, became very profitable.

"When this year we cut the price of cars we cut them below our cost figures of production and for about a month we sold at a loss. But of course we caught up on our own price. We found ways and means of cutting expenses that made the losing price a very profitable one. I am quite certain that if instead of estimating what the consumer would pay and pricing accordingly, we had taken our costs and found the lowest price we could sell at, our business would to-day be dull instead of being better and more profitable than it has ever been."

"During the war, continues Mr. Ford in a recent article in System, "we had considerably lessened our efficiency, unconsciously, of course. We had acquired certain luxuries—although we had never thought of them as luxuries. We employed 15 men per car per day. Now we are employing 9 per car per day. We made that cut by applying the rule that everything and everybody must produce or get out.

"We cut our office forces in halves and offered the office workers better jobs in the shops. Most of them took the jobs. We abolished every order blank and every form of statistics that did not directly aid in the production of a car. We had been collecting tons of statistics because they were interesting. But statistics will not construct automobiles—so out they went.

"We took out 60 per cent. of our telephone extensions. Only a comparatively few men in any organization need telephones. We formerly had a foreman for every 10 men; now we have a foreman for every 17 men. The other foremen are working.

"We cut the overhead charge from $146 a car to $93 a car, and when you realize what this means on more than 4,000 cars a day you will have an idea how, not by economy, not by wage-cutting, but by the elimination of waste, it is possible to make an 'impossible' price. The saving of only a dollar a car mounts up to a big sum of money in a year.

(Continued on page 50)

Production of Dies on Accurate Cost Basis

Standardizing Parts—Careful Study of Details Necessary—Economy of Unit Sizes—Record of Each Operation Kept—Methods of Manufacturing Dies for Jewelry—Details of Construction—Quantity Required a Big Factor.

By CHAS. E. HALL

IN THE following article, an attempt will be made to briefly outline the method adopted in a manufacturing jewelry plant, in the production of their blanking and piercing dies.

We occasionally hear plant managers make the statement, that "there is no money made in the tool-room" and they seem to regard this department as a necessary evil, which must be maintained, and the excessive cost of the tools, etc., added to the cost of the final product. If one is manufacturing articles in large quantities, the additional cost per unit is perhaps negligible. But why not have the tool room on a paying basis as well as any other department?

A little attention given to standardization of such parts as may be in general use, and having them made up in small or large quantities, varying with the requirements in the particular plant, will result in a substantial saving on each job as it comes along with the added advantage of getting it out sooner, which makes for quicker deliveries and future business. This is of special importance when orders are not as plentiful as the sales department would like. These parts may be numbered or lettered and the cost figured on each separate lot. This, divided by the number of parts in the lot, gives the cost per unit, which can be charged against the job in hand as it comes from the stock room.

Study Work Closely

Now fully realizing that perhaps no two places are alike in regard to product or methods, but speaking generally, there is usually some point at which a saving may be effected by careful study of the various circumstances; and in plants where metal stampings are being manufactured, these suggestions can no doubt be adopted to advantage. In the plant referred to in this article, the blanks are necessarily small in comparison with the general run of metal stamping, and consequently but few standard parts need be kept in stock.

Standard Die Blocks

The question has been raised on one or two occasions, "Why do you use the same size of die block for a very small blank, as for one of larger dimensions, when tool steel prices are so high?" The answer is: The reduced cost of standard parts, made up in quantities, more than makes up for the additional use of tool steel as we will attempt to show.

In this shop, the die block which almost covers the entire field is about 2½ in. x 2 in. x ½ in. and weighs approximately 1 lb. before machining. Now suppose these to be made up in lots of one hundred. Then 100 lbs. at 35c. a lb. = $35 for tool steel. Now if these be made up singly, and each block cut to minimum proportions with a saving averaging say, ¼ lb. per block, we have a gain of ¼ lb. x 100 x 35c. = $8.75 per hundred blocks. But you would also have one hundred "set ups" on the shaper, much greater time being taken on each block, and the innumerable delays which inevitably accompany the changing from one machine tool operation to another, and with the high labor costs, far outbalancing the comparatively small saving in tool steel.

Again, fewer press bolsters are required which is another saving, both in money and storage space. By having these parts ready for use, each job is completed sooner (as before mentioned) than if it had to be done with each order, which is a point to be remembered when work is wanted in a hurry; and in this shop prompt delivery receives foremost consideration and very often secures orders which might otherwise go to a competitor, especially when estimates have been pared down to a very close margin. These reasons, we believe, sufficiently justify the small additional tool steel used.

Without taking up the various sizes of standard parts used, let us consider the aforementioned size as an example, viz 2½ x 2 x ½ in. The lengths are chalked off on the bar and cut in half. The two halves put in the saw again and cut into four. Then the four short bars are put in together and the blocks cut off the required lengths four at once, the saw being attended by an apprentice, who, by the way, does all the work on the blanks. They are then planed back and front in the shaper one at a time. This method we find quicker than shaping longer pieces and cutting off afterwards, because all our work on the shaper being very short, the countershaft is speeded up to the limit which gives good production results. A pair of bevel parallels are provided of the required angle and the "faced" blocks held between them in the vise, ten at a time and the angle planed on the edges Fig. 1.

The faces are now smoothed off on an emery covered lapp and the "lot letter" (or number) stamped on the end of each block and charged against each job as used. The standard punch blanks are about 3½ inches long over all, see Fig. 2. The shanks are 1 in. x 2 in. with —.003 in. tolerance on the diameter and

— ENLARGED —

Fig. 1.—Edges planed at angle. Fig. 2.—Standard punch block. Fig. 3.—Locating impression. Fig. 4.—Intersecting lines on die block. Fig. 5.—Die relieved. Fig. 6.—Relieving punch. Fig. 7.—Work. Fig. 8.—Pilot depression.

are made from 1¼ inch. round annealed steel. They are cut off the required length, centered, and the shanks turned to the desired dimensions. Then holding the shank in a universal chuck, the center mark is turned out and the end smoothly faced, the lot letter stamped on the end of the shank, and the cost figured as before.

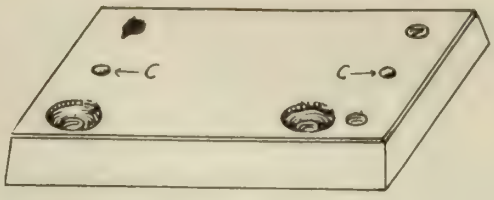
As nearly all the work in this plant is embossed, and often of intricate outline, the method used to transfer the shape of the blank to the punching die block is as follows:—A die and punch blank is secured from the stock room and the cost of each entered on the order. The smooth faces of both die and punch blank are sandblasted and coppered. Special mention is made of the sandblasting as it leaves a fine dull surface on which, when coppered, the faintest mark is easily discernible. A piece of annealed steel about ⅛ inch or 3/16 inch thick, and just slightly larger than the blank is placed on the embossing die and a light blow given it with the drop hammer. This gives a perfect outline of the article.

Two fine lines at right angles are scribed across the face of the impression thus obtained, and a file mark made on the edge at the end of the line as shown at A. A. Fig. 3. This is hardened and the temper drawn to a purple tint and impression placed downwards on the coppered die block, on which two fine lines at right angles, and intersecting in the center of the block, have been scribed, Fig. 4. The marks on the edges of the "print" are lined up with those on the die block, which insures it being placed centrally, and held in place by a couple of pieces of soft wax of any kind pushed against opposite sides of the print. Usually it is not necessary to use the wax; but it is resorted to should the print for any reason have a tendency to move. It is then struck lightly with the drop hammer o screw press, which gives a positive and accurate outline of the embossed blank, regardless of the shape of the contour, and also one which is readily seen and cannot be obliterated.

Marking the Dies

The marked blank is then drilled for the stripper screws, the back of the block relieved under the impression, by drilling or turning to within about ⅛ in. from the front of the die, Fig.5. (the exact length of die wall being governed by the character of the outline) and the impression usually sawn out with a jeweler's saw, if small, or drilled out if larger, filed up to the line on a die filing machine if the impression is over ¼ inch. in diameter. If smaller than this it is filed up by hand.

The majority of these dies are quite small and usually have a few ugly points projecting into the outline which sometimes make it difficult to obtain needle files small enough to negotiate them. In such cases the files are carefully ground down very thin and used for finishing only. The finer sizes of jeweler's saws, as well as fine half-round and knife-edge gravers are a great help in cleaning out a corner rapidly and well. With the impression marked in this way which only takes a few minutes, it is only necessary to file till the line disappears, and there is no necessity of working templates through the die. No template need be made at all as the print takes its place.



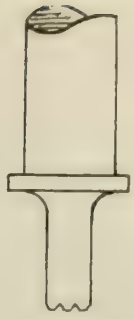


FIG. 9.

FIG. 11

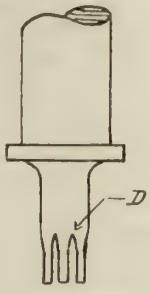

FIG. 12

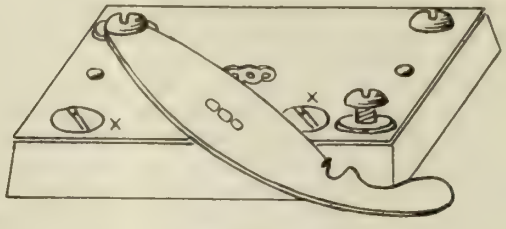

FIG. 10

Fig. 9.—Drilling in standard blocks. Fig. 10.—Arrangement of stripper. Fig. 11—Punch notched for fitting. Fig. 12.—Die outline on punch.

By using an eye-glass occasionally the slightest trace of the outline can be rapidly seen, and extreme accuracy, coupled with speed of production, is easily obtainable. The hand filing is done in a vertical direction, the block being placed face up on the work peg projecting from the edge of the bench, so that the die-maker has his eye constantly on the line. The matter of clearance is largly one of practice and a good man does not have to refer to the back of the die very often. Working in a seated posture also tends to speed up production as it is less fatiguing than the twisting and turning which accompanies filing at the vise.

The die is then heated in a gas furnace of the semi-muffle-type and hardened in the usual way. The face of the die is then polished on a very fine emery lap and the temper drawn evenly by laying it on a heated iron plate. By wiping the polished surface with a clean oily rag the changes in color are more easily noted than on a dry polished surface.

Fitting the Punch

The die proper is now ready. A punch blank is clamped to the face of it and the outline scribed through the back of the die. It is then placed on a milling attachment on the lathe, specially fitted up for this particular work and milled as close to the line as possible. The eye-glass is again used on this operation and results in very little metal being left to broach. Again using the eye-glass it is beveled on the end all round by hand filing at about a 45 deg. angle till the scribed outline just disappears. The punch end will then perfectly engage itself in the die, and a slight blow with a hand hammer will make it snug which aids in setting up in the screw press for broaching.

Broaching the Die

When properly set, the press is brought down about 1/32 inch in most cases, (the exact amount depending on the character of the die), the punch removed from the press and the burr raised in broaching taken off. The operation is repeated till the punch is broached to a sufficient length. If but a few thousand blanks are all that will ever be wanted, about ⅛ inch or even less, will be far enough to broach the punch. Any more time expended to make a "pretty" job is wasted.

Usually with each succeeding operation, the broaching can be carried a little farther than the preceding one, because when removing the burr any part with an excess of metal is easily seen and removed at the same time. When the broaching is completed, the punch is relieved in the lathe as shown at Fig 6, and cleaned up to a regular shape. It is then hardened on the end and the temper drawn back to a greater extent than the die, and when the stripper is made it is ready for use. It will not be necessary to go into details in regard to the stripper as it is familiar to anybody who may be interested in this article.

In regard to piercing dies, nearly all our punches are made solid, and it is

seldom we have occasion to use inserted punches.

For the purpose for which these dies are used by us, we find from experience that the solid type are more accurate, no possibility of one becoming loose, and possibly ruining the die, and they have a long life of usefulness.

As some of the blanks to be pierced are very small, it follows that the piercing punches from their slender nature must not be longer than is necessary, therefore the stripper must be as close as possible to the face of the die. Fig.7 may be taken as a simple example. The blank in this case is an I. O. O. F. emblem and is 9/32 in. long and 3/32 in. wide, outside measurements. Consequently the pierced holes in the links will be about 1/32 in. wide in the center link, and still less in the smaller ones. These are first embossed from small rectangular pieces of metal cut off in gauge on the shears, just sufficiently large to cover the impression in the embossing die. They are then struck up, trimmed out on the banking die, and finally they are pierced in the links. A small depression in the embossing die, close to the edge of the impression, Fig. 8, acts as a pilot in trimming out, a corresponding depression being in the trimming die. This insures the blanks being cut out the same way each time, besides making the "feeling in" easier and quicker.

Construction Features

The piercing die is made as follows:—An impression is struck from the embossing die, trimmed out, and the small holes to be pierced, accurately worked out by hand. This is used as a template. One of the standard blocks is drilled and tapped as shown at Fig. 9, (five holes in all) for 10 x 24 machine screws. The holes at c.c. are just "spotted" and are used for locating the guide plate. A piece of cold rolled steel is reduced by re-rolling to about .02 in. thick and cut to the size of the die. A hole the shape of the block is punched in the center on the trimming die, and lightly filed all round to allow the blank to enter easily, but snugly. In fitting the emblem, the plate must be held "burr side up" ad clamped on the die block in this position. The holes are marked from the back of the die and the plate drilled. The guide plate is now screwed in place and the holes x.x. Fig. 10, countersunk, as the screw heads here must be flush to enable the stripper to swing over them.

The stripper in this case is made as shown in Fig. 10, and has a thin washer under each end just thick enough to let the stripper clear the blank when placed in position. The screws which hold the stripper go but halfway through the block, and when finally screwed down just firm enough for the stripper to swing, two screws are put in from the back to lock them securely and are cut off flush. Of course these screws are put in after the die is hardened. With the die still soft and the guide plate securely fastened, a ball punch is held on the plate over the "spotted" holes and struck with a hammer, which leaves a concave depression in the plate and conforms to the hole beneath it. This makes a quick and positive job of re-locating the plate when taken off at any time.

Filing to Template

Now with the template in place, the piercing holes in the die are worked out after first relieving the back of the block. The filing is continued till the operator can just feel the template with the file which gives positive results, and eliminates eye-strain, attendant on working to a fine line. The die is then taken apart, hardened and tempered and is ready for the punch.

In this case the punch would be too small on the end to mark through the die, so it is roughed out to approximate size and the end filed as at Fig. 11, and the little tips beveled. This is held on the die and struck squarely on the end with a hammer, a very light but smart blow being all that is required. This leaves the exact outline of the die and it is milled to this line for about ½ in. back, leaving the punch as shown at Fig. 12. The space between the punches are not carried back any farther than will just clear the stripper and leave a little allowance for grinding if the punches become dull. Also the ends of these spaces D—Fig 12, should be nicely rounded away as shown, to give a gradual thickening of metal towards the base of the punch. This makes a stiffer job and eliminates hardening troubles. It is now carefully broached, the ends squared up, hardened and tempered.

The objection may be raised that if one tip breaks off the punch is ruined. This is true. But on the other hand, it is quickly replaced, and from experience we find that breakages seldom occur. In fact during the last ten years we have had but two misfortunes of this nature and they could have been avoided. The press hand neglected to close the stripper, the punch picked up the blank, and in attempting to remove it, broke one of the ends. There are many dies of this and similar kinds in the plant and the way they have stood up should be an argument in favor of the solid punch, independent of the fact that they can be made at a decided saving over the inserted method. More tool steel is used, but if the cost is less, why worry!

Of course what has been said by no means applies in all cases; neither is this article intended to be a "guide to diemaking," but simply to set forth briefly the method used by this firm in turning out its product. Like all other places, jobs occasionally come in which cannot be handled in this manner, and consequently receive different treatment, according to the exigencies of the case. The points we would specially emphasize, are the importance of an accurate cost system throughout the plant. Don't waste time in broaching a punch too far back, if the die is to be used for just a few thousand blanks and never used again. Make for rapid deliveries wherever possible, and finally, don't neglect your trade magazines, especially the advertising sections, and take full advantage of all new tools and special equipment likely to meet your needs and which tend towards better work and quicker production.

VALUES OF NICKEL AND CHROMIUM

The discovery by Mr. A. L. Marsh, in 1905, of the remarkable properties possessed by alloys of nickel and chromium, has a far-reaching effect upon the electrical heating and cooking industry. It has almost revolutionized it. "Prior to that time," says a writer in the Engineer, "electrical heating elements were unreliable, could be operated at only a low temperature, the dissipation of energy represented by the watts consumed per square inch of heated surface was small, and under the best conditions the elements possessed only a short life. The modern electric heating element possesses none of these disadvantages, and its present satisfactory state of development is directly attributable to the production of nickel-chromium alloys.

"The actual manufacture of nickel-chromium alloys is among the most difficult problems in metallurgy. Both metals melt only at very high temperatures, and the problem is further complicated by the fact that at its melting point chromium is readily oxidised and nickel is a solvent for carbon. The slightest variation in the process of manufacture is apt to affect results at some later stage, hence the most careful control must be exercised at all times. The alloys are commonly made in the form of rods of about ½ in. diameter, and the process of reducing the rods to the sizes required is now reduced to a comparatively simple process, alongside of the previously adopted methods.

CALL THE AMBULANCE

Septimus Wagge met his chum the other day.

"I say, Bill, I watched a wonderful machine at our shop this morning."

"And how does it work?"

'Well," was the reply, "by means of a pedal attachment, a fulcrum or lever converts a vertical reciprocating motion into a circular movement. The principal part of the machine is a huge disc that revolves in a vertical plane. Power is applied through the axis of the disc, and work is done on the periphery, and hardest substance by mere impact, may be reduced to any shape."

"What is this wonderful machine?" asked Bill.

"A grindstone," was the reply.

How to Place Employees to Best Advantage

Outlining a Successful System—Learning What a Man Knows—Trade Test a Paying Investment—List of Questions Asked—Testing a Workman's Ability for Service.

By RUSSELL J. WALDO

VALUABLE data have been published during the past two years relating to selection of employees, who can operate various complicated jobs without organizations. Although the methods discussed have been good if used by the man who made them out, they have in the writer's opinion, left entirely untouched one of the most valuable elements of aiding the interviewer in determining with greater accuracy how much a man knows of the task for which he applies.

In the majority of cases the practice is to ask and accept the applicant's information without requiring him to give definite information of what he knows. It is not enough to ask a man how long he has been with a given firm or what has been the extent of his experience, where he has worked or similar questions. Some method must be brought into use which will actually gather how much he really knows, not how long he has been gaining it.

If manufacturers expect to compete successfully with other corporations in lowering their prices they must adopt some system which will reduce their production costs. They must rely upon some method which will place every man who applies for a job in the position he is best fitted for and the one with the most responsibility. To do this requires the use of some method which will successfully draw the necessary information out of the applicant, then allow him to convince the interviewer that he knows what he is talking about. This is best done by the trade test, which is the purpose of this article. Inefficiency in the workman will show up in greater production costs and many of our larger industries seem content that they have selected the most efficient men for their respective tasks, when in reality they have not gone into details of the worker's experience at all.

Trade Test Advantages

The trade test which the writer worked out for use at the Studebaker Corporation at South Bend, and which was used by him during one of the most severe labor shortages this country has ever seen, not only fitted the task there, but if the same fundamental principles are worked out by any employment executive for their own use in other plants are capable of gaining the same results, equally accurate and dependable.

This can be proved in this way. Regardless of where a given machine is being used, the methods of successful operation remain the same whether they are used in an automobile shop or in a machine tool plant. The requirements for the operator remain the same, therefore the tests used in one plant—except for some additions which might be advisable for that particular plant—can be equally successful in another plant using the same machine.

For the benefit of business leaders who are trying to reduce their production costs, the writer outlines the tests as used by him, not as a system one hundred per cent. perfect—as none can be this—but a method that will prove the greatest investment possible in connection with the employment division.

The illustrated trade tests permit a man who knows but little about the given task to select employees with equal accuracy as the man who knows the task well. With the test he is in a position to convince the applicant that he must gain the place through actual ability and not be able to bluff his way through. To the man who will carefully weigh every reply and consider a man's relative merits, this test is capable of wonderful results. Others would be unable to gain results with any method except on perhaps machines they had actually worked upon. I have had men who failed in the tests, as well as those who have made good in them, frankly tell me they were the fairest sort of quesions that a man could expect.

These are not being passed on with the thought that others will use them exactly as they are stated, but are given with a hope that the findings so far will permit others to work out similar tests in their own way and thus assist organizations to reduce their production costs.

What the Test Is

The trade test is a fair opportunity for the applicant to convince the interviewer that he knows what he is talking about. It gives him a chance to actually show that he understands his work. The general belief is that the trade test is a catchy sort of method to make a fool out of a man. By the use of pictures a man is allowed to get nearer to natural conditions of the job and to point out things which he would not have thought of unless he were facing the actual machine. It is a carefully outlined method of procedure for the interviewing of applicants, which has for its main purpose that of making the interviewer doubly sure that he has not omitted some important question. It proves itself to be a legitimate method for the interviewer to determine a man's ability. The writer has failed to find an efficient man who could not point out equally well parts on a picture that were found on the original machine and tell of their functions.

The careful working out of these tests eliminates much that was formerly useless and burdensome, and which accomplished no definite purpose. In addition to this the use of pictures allows for closer questioning of the applicant. In working out the tests such questions as the following might be asked to show if the worker had a deep interest in the machine and took interest in studying it. Where is a certain automatic screw machine made? Where is a certain machine tool firm located? What do they make?

Mathematical problems such as are found in usual practice are also helpful in showing a man's ability to figure them. Spelling of names of tools and other terms used is also helpful. Reading a portion of a page from the operator's handbook of the machine he seeks

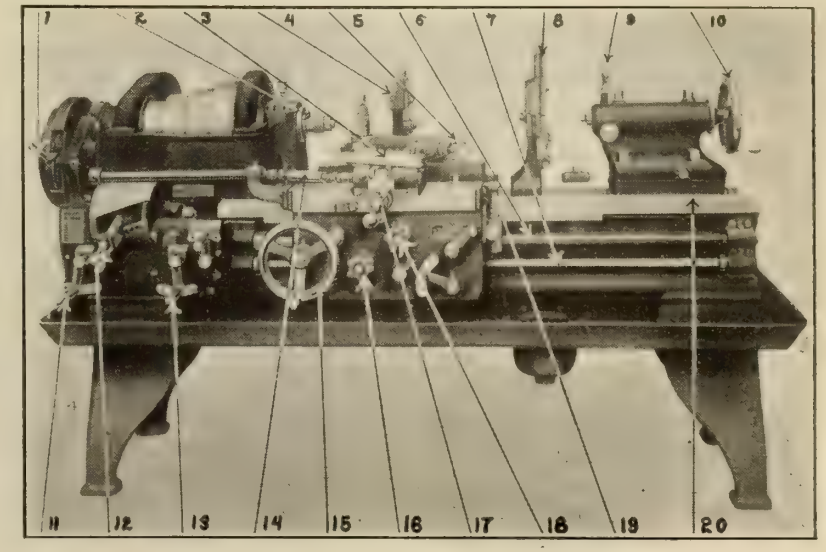

Fig. 4.—Diagram to test knowledge of machine parts.

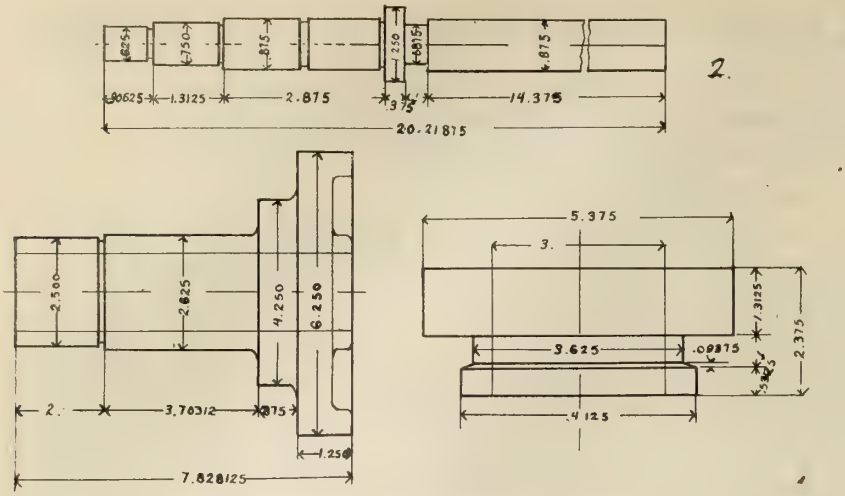

Fig. 3.—Method of testing knowledge of drawings.

a place upon, is also of value if the interviewer has the time.

One of the writer's first drawbacks in making out these tests was the overloading of the test with questions. However, later, questions were combined, some removed and other changes added that made them more valuable for the task of selecting. It would be useless to give a hard and fast rule regarding procedure. Typical questions may be used to illustrate this outline but the interviewer may make out a more satisfactory list for his own use when he knows the nature of the work the applicant will be required to do.

The Job Specification

Of first importance is the job specification. The writer shows with this outline the specification used for journeyman millwright. This is shown below.

Millwright Journeyman.

Duties—Laying out and installing machine tools, shafting and the maintaining of them.

Qualifications—Must be able to layout his work from blueprints or rough sketches, set up and keep in repair any and all machine tools used in the plant.

Should be able to install gravity conveyors, belting, cranes, machine tools, shafting, pulleys, hangers and other general equipment.

Should be a practical belt man fully capable of maintaining belting, should be able to erect stringers and hanger bases, and be able to handle blocks and jacks quickly and safely.

Must be capable of handling large machinery with the use of blocks, jacks skids, cribbing, in both favorable and unfavorable conditions.

Should be familiar with concrete work as concerns his own particular duties, especially foundations.

Should have had sufficient experience to supervise installing equipment and handling men to gain their best work.

It is highly important to use great care in making these out. First it must be known exactly what an employee must do once he is at work. There are various grades of millwrights controlled by the section of the plant they are in. However, in most plants the millwright must be one that is capable of being transferred to any department with equal results.

The job specification is nothing more than a carefully made out synopsis of what the millwright must do once hired and placed at work. In the requisition for employees it is possible for the foreman to suggest that a man, with certain qualifications, can be used in a stated department, if he has had no experience in other branches. The purpose of job specification is to show the interviewer what is expected of the man, and permits him to be more specific in selecting the applicant.

Question List for Applicants

Below is shown a reproduced page from my book showing typical questions asked.

Testing Workman's Ability

What is the capacity of the Cincinnati Automatic?
What are the spindle speeds?
What are the feed speeds?
What are the speeds in R. P. M.?
Do finished parts and chips drop in the same place?
How are tools controlled?
Of what metal are the spindle bearing boxes made?
How does the machine revolve?
Does it use right or left handed tools?
How many spindles can be locked in a stopping position when the machine is running?
How many tools can be operated at one time?
How many cross slides on the machine?
For what kinds of tools are these used mostly?
Can machine be run without chucking and feeding while setting up?
How many and where are the stopping levers?

In this case the questions were used in connection with the automatic screw machine construction. In making out these questions it is important to determine exactly what a good man should know, then build the test questions around the factors.

In Fig. 3 is shown three drawings. The purpose of showing these is to determine how much a man knows about the reading of drawings. Questions asking for certain dimensions are worked out. Questions for apprentices were much simpler than those for the experienced operator. The applicant was asked such as the meaning of turret, R. P. M., define lathe apron, micrometers, chuck and other parts of the machine. The skilled operator was asked questions regarding the actual operation of the machine similar to the questions shown in Figure 2.

Such questions as:—Where do you spend your evenings? Why are you seeking a place with this firm? If you had the job of your choice would you be willing to study and improve your ability? If you could have any job you choose what would it be? Do you have a hobby? What kind of reading do you prefer? These questions were very helpful in deciding upon the desirability for employees in exacting places.

The Use of Pictures

Illustrations in various forms have proved of great value in selecting employees. The picture shows up a given machine or part as it actually is. In Fig. 4 is shown a marked photograph of a 16 inch high duty tool room lathe. There are twenty parts indicated which correspond to the list below.

1. Handle on quadrant for relieving attachment drive; 2, Spindle nose with draw-in-collet; 3, Top slide of compound tool rest; 4, Follow rest; 5, Compound rest top slide adjusting screw ball crank; 6, Lead screw; 7, Feed rod; 8, Steady rest; 9, Tailstock spindle clamp lever; 10, Tailstock spindle moving handwheel; 11, Feed mechanism back gear lever; 12, Sliding tumbler for feed changes; 13, Feed mechanism back gear lever; 14, Telescoping shaft for relieving attachment; 15, Carriage moving handwheel; 16, Longitudinal

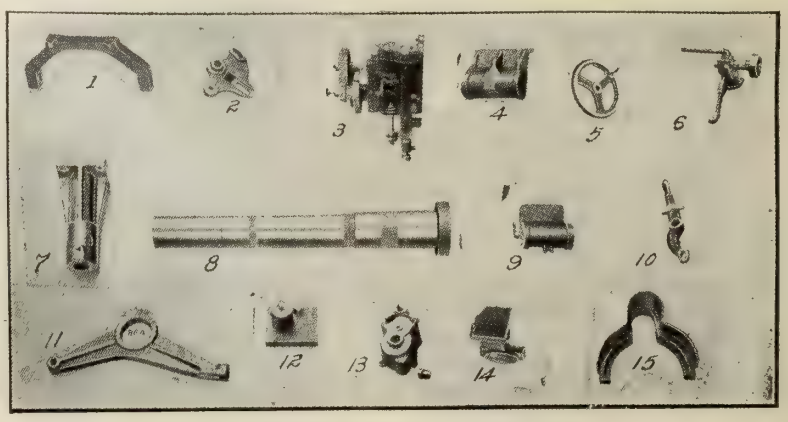

Fig. 6.—Individual test sheet of machine parts.

feed control knob; 17, Tool rest cross feed screw ball crank; 18, Cross feed friction control knob; 19, Chasing dial for thread cutting; 20, Front way or vee of bed.

With the aid of these, many questions can be worked out. The wri.er did not always refer to definitely arranged questions, but asked the function of some part by number, or to give the number of some part and have the applicant tell the function of it.

In Fig. 6 is shown an individual p test for a turret lathe, as used by the writer. The object of this test is to require the applicant to name the parts shown on the sheet. The parts are not assembled, yet the average experienced operator can easily name them. Great care must be exercised, however, in selecting the parts to be used to make sure that they are those that should be known by the workers. The list of parts kept before me in my work is as follows:—

1, Headstock Bracket; 2, Main Feed Box Quadrant; 3, Fine feed driving pinion; 4, Rapid traverse friction housing; 5, Carriage apron handwheel; 6, Oil Pump; 7, Drill Holder; 8, Headstock spindle; 9, Turret apron pilot shaft; 10, Feed change level; 11, Drill support; 12, Cross slide; 13, Cross feed housing; 14 Rapid traverse screw bracket; 15, Friction gear shield.

Some Miscellaneous Tests

The missing word test is very helpful. The writer found that by using these the applicant was not only checked as to his knowledge of the machine but he was checked as to his ability to think fast and clearly. The object is to have him fill in the necessary words as he reads. Following are ten sentences regarding the automatic screw machine used in the missing word test. The sentences as shown are from the writer's copy. The words shown in parentheses are those omitted in the applicant's copy.

1.—The master cam drum is on the (left) hand end of the machine.

2.—A (hand control) wheel is provided on both sides of the machine.

3.—All tools are held in contact with cams by (springs).

4.—For (left) hand threading the threading mechanism action is changed.

5.—This automatic is provided with (four) cross slides.

6.—The chucks are of the (stationary) type.

7.—Stock spindles revolve in a (forward) direction.

8.—The machine turns any length up to (three) inches.

9.—Cross slides are contro'led by a (positive stop).

10.—In case of accident the machine is provided with two (safety clutches).

In Fig. 7 is shown a typical operation test. This shows ten operations being performed upon a turret lathe, the object being to have the applicant name as many of the operations as he possibly can. The detailed list follows:—

1, Machining cast iron bearing bracket; 2, Machining steel cast genera'or frame; 3, Machining steel cast gear blank; 4, Machining cast iron driving gear; 5, Machining malleable iron wagon hub plate; 6, Machining malleable iron hub; 7, Machining steel cast rear truck wheel; 8, Machining steel cast gear blank; 9, Machining cast iron gear blank, first operation; 10, Machining cast iron gear blank, second operation.

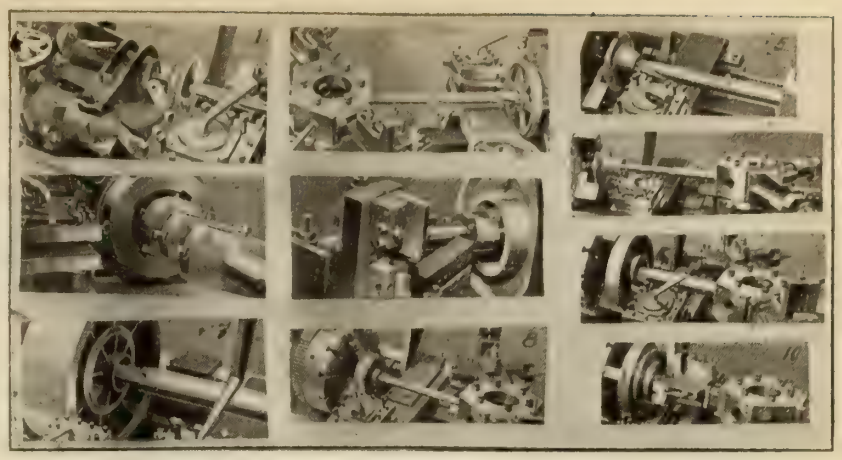

Fig. 7.—Typical operation test sheet.

It proved most interesting to ask the skilled operator to name all the attachments he could for a given machine. This practice is not always used, yet the more the man has to say about his experience the more desirous the writer would be to have him name the parts. Tes's with pictures of marked devices such as dividing heads, milling attachments for automatics and similar devices used in connection with various machines were prepared and used where the operator would be required to know the duties of them.

Future Value of Trade Test

Executives everywhere have heard much regarding the trade test and the possibility of its reducing their production costs. Now that good men are to be had, plant officials should adopt some method whereby they may know these men when they appear. To this end I have outlined the picture trade tests which proved so successful in my work at the Studebaker plant so that others might become familiar with it and find some'hing that would be of value in reducing their produc'ion costs. The idea is the same regardless of where it is used even if more must be added or some removed.

The Harding Co., of New York has just issued a new catalog, No. 12, covering their improved line of Quigley Fuel Systems and other equipment relating to the handling and burning of pulverized fuel. The bulletin treats on the subject in a thorough manner and is profusely illustrated.

Don't fail to subscribe for a trade paper, you owe it to yourself and your dependents to be efficient.

DON'TS FOR MACHINISTS

Don't grind round corners on the emery wheel.

Don't stamp steel letters or figures into cast iron scale.

Don't run the point of your lathe tool into the mandrel.

Don't tighten bolts and nuts tight enough to strip their threads.

Don't force a cap screw in a newly tapped hole without oiling it.

Don't use one mandrel to drive another out of a piece of work.

Don't try to drill a piece of work unless it is properly supported.

Don't put a mandrel into a newly bored hole without a lubricant of some kind on it.

Don't let the point of your drill touch your work and run along without feed on it.

Don't put a piece of work on centers unless you know that the internal centers are clean.

Don't turn a reamer backwards.

Don't file against the scale of cast iron.

Don't use a monkey wrench for a hammer.

Don't try to make a finishing cut on scale.

Don't drive a key too hard while fitting it.

Don't run a machine with the belt too loose.

Don't nail a piece of wood to the ceiling rafters to make the belt stay on.

Don't keep on using a drill after it begins to squeak without investigating the cause.

Don't straighten a heavy job between the lathe centers and take it for granted that the centers will run true afterwards.

Don't take a complicated piece of machinery apart without marking it properly to facilitate reassembling.

Don't take the live center out of a lathe without marking it, so that you can put it back in the same place.

Don't let the tail of a lathe dog pinch against the bottom of the slot in the face plate.

Don't drill sheet brass with a twist drill, use a flat or farmer drill.

Don't forget that a good center punch can be made from an old round file.

Production of Gears by the Rolling Process

Great Pressure Required—Machines of Heavy Construction—Gradual but Speedy Forming of Teeth—Die and Blank Positively Driven—Allowance for Shrinkage—Redressing Die Rolls.

IN THE actual process of rolling gears, the blanks are heated to a temperature of between 2,000 and 2,100 degree F. and are mounted on the work arbor of machine shown in article. They are securely clamped in place by means of powerful automatic chucks, mechanical, pneumatic, or hydraulic, the arbor carrying the blank and that carrying the die roll having been adjusted to the proper angle in respect to each other required by the type and dimensions of the gear to be rolled. The blank and die are then rolled precisely in synchronized contact under a rolling pressure of from ten to twenty tons. As the rolling commences, the die roll is automatically advanced to positive contact with blank.

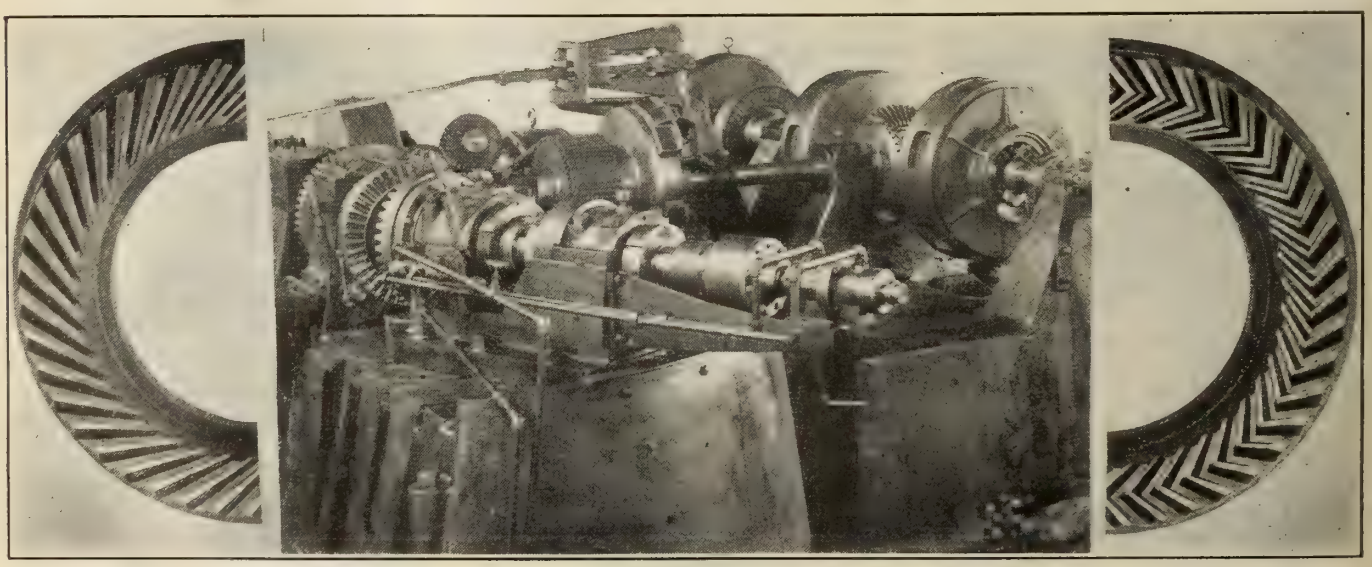
As the rolling continues at high speed, the die roll is advanced until the teeth of die have penetrated to nearly full depth in the plastic gear blank. The advance is then slowed somewhat until the formation of the gear is completed and die and gear are in full engagement. This movement of the die roll is automatically produced by means of a positive cam mechanism which accomplishes a regular and constant progression in the first stage, and a gradual retardation as the die approaches full depth.

This cam mechanism is also designed to assure full penetration of the die roll tooth before heated blank has cooled below its critical temperature, and then continue the rolling with no die advancement until the blank has cooled somewhat below this point. As the rolling is done at an average speed of from four to seven hundred r. p. m., depending on the size of the machine and gear rolled, it is apparent that advance of the die roll per revolution is very slight. This assures a thorough kneading and working of the metal of the blank, and permits metal to flow freely and evenly. The fact that both die and blank are positively driven and accurately synchronized assures the die teeth penetrating the blank radially in exactly the same position on each revolution, and eliminates any slippage or tooth distortion in the finished product.

During the operation, the die is cooled by a stream of water directed against its face at a point farthest from the contact with the heated blank. Through the entire process, consuming only a few seconds, the temperature does not rise above a heat easily bearable to the hand. The chilling effect of the comparatively cold wet die on the heated blank causes a sudden contraction and consequent loosening of the scale formed, which is then thrown off by a centrifugal force resulting from the high speed of operation. Since the rolling is continued until the blank has cooled below the critical temperature, or in other words until after the formation of forging scale has ceased, the finished product of the process is free from scale and the formed teeth are not only perfectly shaped but are also highly polished on all contact surfaces. This fact eliminates any necessity for further finishing operations, except on the bore and faces of the hub, and on the ends of the teeth. For these operations, which may be semi-automatically perfomed, the gears are chucked on the rolled teeth, thus assuring accurate centering.

In order to assure the highest possible degree of precision of tooth form, machines designed for the production of accurate gears are equipped with additional mechanism for frequently and automatically reversing the shafts carrying the die and blank. This automatic reversing, or oscillation, at somewhat reduced speed, varying from about 80 to about 200 r. p. m., during the forming of the teeth, and nearly to the point of full engagement, assures displacement and building up of metal to an equal degree on both sides of the teeth, thus producing a symmetrical tooth.

The full cycle of operation on the oscillating type of machine, automatically controlled, is as follows: High speed direct rolling, the die advancing to positive contact with the gear blank; oscillating rolling at reduced speed until the teeth of the die roll reach within about 0.010 inch of full depth; planishing at high speed direct rolling until the die roll teeth engage the gear to full depth, and high speed withdrawal of the die roll.



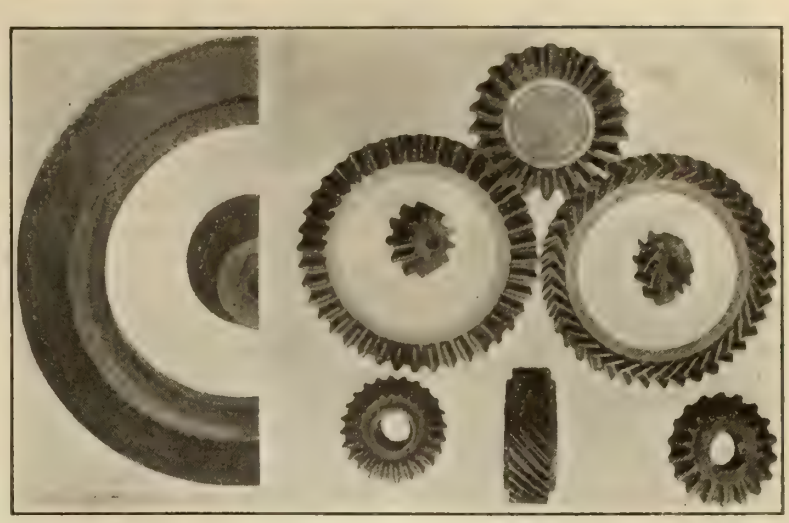
Shrouded Gears

The die rolls are somewhat narrower than the gear blanks and the effect of this is the production of gears which are partially or fully shrouded. Consequently if it is desired to strengthen the weaker member of a pair of gears, the shroud may be left on, either entirely or partially, or the shrouds of the two gears may be so proportioned as to equalize the strength of the two, increasing that of the combination.

Proportioning Die Rolls

As the actual operation of moulding the plastic gear blank ceases when the

We are indebted to the Anderson Rolled Gear Co. for the accompanying data and cuts.

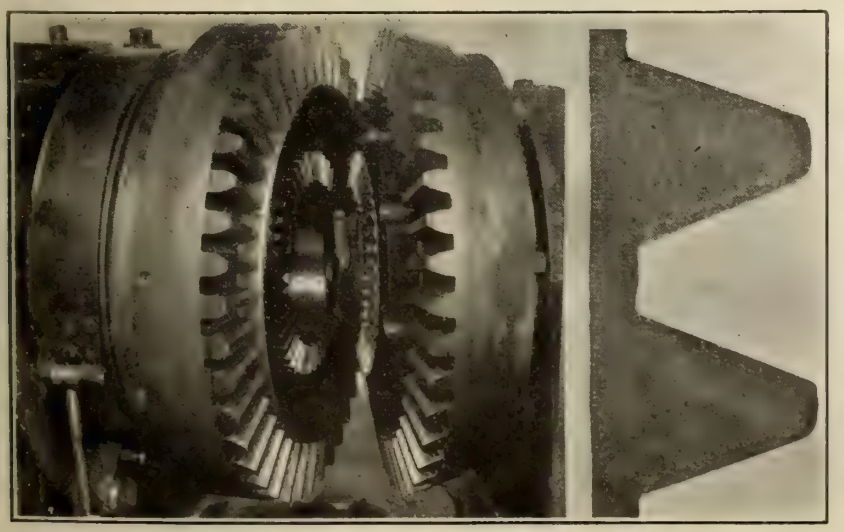


Centre.—Rolled gear machine showing operator's side. Left.—Two-piece ring die as cut. Right.—Two-piece die assembled for rolling herringbone gears.

heated blank has cooled below its critical temperature, and before there is any appreciable increase in the temperature of the die roll, it is of course necessary to design the proportion of the die roll for moulding the gears at that temperature. Consequently the dies must all be somewhat oversize as compared with the finished gears at normal temperatures. In designing the dies, this allowance for shrinkage of the moulded gears can only be determined empirically. However, the laws governing the action of metal under the fluctuations of temperature and the co-efficients of expansion have been so accurately established that a high degree of precision is obtainable in the proportions of the die rolls. Die rolls properly made and proportioned as above should as a rule permit of the production of at least five hundred accurately formed gears before any redressing becomes necessary, and should also permit a considerable number of redressings during the life of the die rolls.

All types and sizes of die rolls having the master form gear teeth can be redressed whenever wear or dulling makes it necessary. It might at first appear that this finishing, especially in the case of the gears of the spur type, would immediately introduce appreciable inaccuracies in the product due to the inevitable slight reduction in the diameter of the die roll, which must result from each refinishing. This would undoubtedly be true if the moulding were accomplished by a knurling process, that is if the blank were driven by the die roll or vice versa. It must be remembered, however, that both the gear blank and the die roll are mounted on shafts which are positively and independently driven and whose rotations are exactly synchronized by separate timing gears.

Thus, the angular distance between the teeth moulded on the blank is controlled and maintained constant, regardless of any slight reduction in the diameter of the die roll, or the size of the die teeth, the only effect of this reduction in diameter if it is appreciable at all, would be a very slight creep between the die and blank when in motion. This creep, however, would be held uniform and constant by the timing gears and, as the thickness of the molded teeth is dependent on, and controlled by, the width of the tooth space of the die, even a considerable amount of creep may be readily counteracted by reducing the thickness of the die roll teeth a slight amount necessary to maintain constant the width of the die roll tooth spaces. This modification of die roll proportioned, however, is unnecessary in the case of the crown or flat bevel tpe of dies used in the moulding of any type of bevel gears. With these forms the grinding of the teeth does not affect the diameter of the die rolls.



Left.—Group of rolled gears. Right.—Shows section of gear and pinion blank before rolling.

Inherent Strength

The inherent strength of rolled gears is due to the effect on the structure of the metal of rolling under high pressure. This process, and the thorough kneading action of the die teeth on the metal while in the plastic state, in addition to building up and compressing the metal into the formed teeth, gradually breaks up the coaster crystalline structure and produces a dense, thoroughly worked and fibrous structure. The minute crystals are rearranged in a trussed formation following the periphery of the finished gear thus tying the teeth to the body and equalizing the structural strains. The elimination of internal structural strains is so marked that no distortion occurs in subsequent heat treatment, and it has even been found unnecessary to use any clamp to hold the gear true in quenching.

The above factors of this rolling process are claimed to materially increase the harness and wearing qualities and make a more uniform result from subsequent case hardening or other heat treatment.

NEW USE FOR COMPRESSED AIR

Compressed air is now being used in quarrying granite, and according to a writer in Popular Mechanics, has been found to have advantages over the usual method when the rock is devoid of joints. The method is as follows:

Two three-inch holes are drilled, a short distance apart and perpendicular to the rock, to a depth of eight feet. after removing the drills, a spoonful of black blasting powder is dropped to the bottom of each hole, tamped with clay, and the holes wired so that they can be electrically fired. The effect of the explosion is to start cracks in the rock at right angles to the holes. This operation is repeated a number of times, until it is certain that the cracks radiate from the bottom of the holes to a distance of about 75 feet. Into each hole, to slightly over half its depth, there is then inserted a one-inch pipe, and the space surrounding pipes in the holes is filled with sand, tamped so as to seal it against air pressure. Connections are then made between the upper ends of the pipes and the quarry air compressor, which continues to pump air at 100-pound pressure, into the holes until the block of rock above the cleavage already formed is torn from the surrounding rock.

Grinding Machine With Oil Feed Control

Developed During Quiet Period—High Traverse Speeds—Sensitive Throttle Valve—Flexibility of Table Movement—Shockless Reverse—Single Control Lever—Unit Type Spindles.

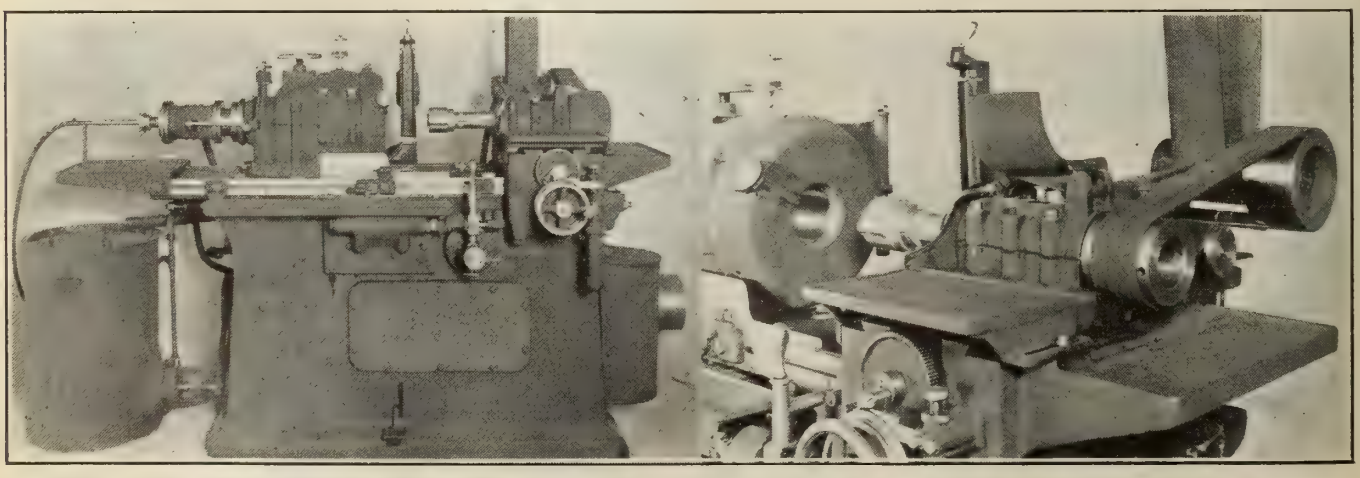
"IN TIME of peace prepare for War," is a well known saying, but several concerns have recently changed this to "In dull industrial periods prepare for the coming activity." They have been carrying on development work during the lull, with the result that they are now able to offer to the trade, new machines with several out of the ordinary features.

Take for example the machine shown. This is a new internal grinding machine, designed by R. L. Morgan, formerly principal owner of Churchill-Morgan-Crittsinger of Worcester, Mass. The Greenfield Tap & Die Corporation, Greenfield, Mass., have recently purchased the former mentioned firm, this now forming a part of the machine tool division with which Mr. Morgan is connected. W. H. Chapman, formerly assistant to C. H. Norton of the Norton Co., is assisting Mr. Morgan in this work.

Referring to the machine we find that the design is based upon the principle of high traverse speeds. The wheel spindle is carried on a wheel slide controlled by a feed-screw calibrated for feed increments 1/4,000 inch on the bore diameter of the work. The work table reciprocates upon ways at right angles to the wheel slide ways and carries a work head for holding and rotating the work piece.

The table traverse speed is controlled by the regulation of a highly sensitive throttle valve which admits oil under low pressure to a distributing valve, controlled by the table limit stops, and thence into either end of a double-acting cylinder and piston mechanism attached to a crosshead on the under side of the table. By a careful application of hydraulic principles a flexibility of table control is said to have been obtained which is practically impossible to get by mechanical means. Table speeds from two to thirty-six feet per minute are employed in the usual range of operation, while maximum speeds of fifty feet per minute are possible in the present designs. Special designs can provide for faster operation should an operator be found capable of keeping up to it.

There are no definite stations of speed setting as in mechanical drives, so that the most minute shading of speed is possible with no difficulty. Valve and piston design provides for shockless reversal due to cut-off and admission being controlled to cause acceleration curves to follow the law of uniformly accelerated motion. The element of time involved to accomplish a reversal is so small that on ½ in. stroke the table will reverse 320 times per minute without shock. A pressure relief valve allows the table to stop without damage when overloaded. This feature also allows accurate positioning of the table for grinding against a shoulder. A screw adjusted table stop locates the table which is held in place under oil pressure. By a combined use of reversing and locating stops, the table can be held to within .0005 in. limit on reversal, without any sacrifice in operating speed.



The work is revolved toward the operator at the top, while the wheel turns away from the operator at the top, the diamond contacts on the back of the wheel throwing the dust down instead of up into the air. Spindle bearing pressures are in the same direction whether the wheel is grinding or running free. This eliminates "hunting" in the bearings and overcomes one source of bell-mouth grinding. The standard spindle provided with the machine are mounted upon ball bearings so installed that thrust adjustment eliminates all shake in either axial or radial pressure action. A good commercial finish, free from chatter is obtainable with these spindles. Where exceptional mirror finish is desired, production rates are sacrificed to some extent and special types of spindles furnished. However the high operating speeds still show to advantage even in this class of work, and "fussy" finishing jobs are said to be accomplished more rapidly than on slower moving machines. The superiority of the machine is claimed to lie in its ability to remove stock rapidly in roughing operations. For holes 3 inches bore diameter or greater, the machine removes at least one cubic inch of hardened steel per minute, floor to floor, assuming a reasonably fast holding fixture.

For large bearing races having straight holes a special type of work head is provided which chucks several races end to end, holding them endwise between a plunger operated by oil pressure and an iris plate mechanism fashioned after a camera shutter. The plunger ejects the load at the end of the operation when the iris is opened. By the use of loading pots this fixture also grinds piston rings, etc. Machines in the field to-day, thus equipped are consistently showing floor to floor time of from ½ to 1/3 that of conventional machines now commonly used for this work. A single machine has ground 25,000 piston rings per 10 hr. day with a helper to load pots. The reason for these results is said to lie in the fact that the following points are featured:

1.—High table traverse allows the rapid exposure of work surface to the wheel face for depths of wheel feed well within the capacity of standard abrasive wheels. The wheel therefore actually cuts away more material in a given time without friction and heat losses attendant upon slow traverse operation.

2.—Rapid sizing is obtained because the rapid application of relatively light

Overcoming Defects in Drop Forge Work

Fundamental Principles—Flow of Plastic Metal—Duplex Forging—Cause and Elimination of "Cold Sheets"—Producing Sound Forgings—Effect of Hammer Blows—Providing Space for Excess Metal—Alignment of Die Blocks.

By J. H. G. WILLIAMS

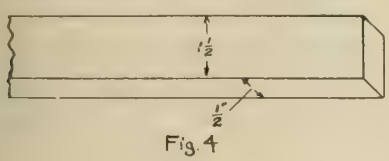
PURCHASERS of drop forgings often are of the opinion that once the dies are made, it is a simple matter to produce sound forgings, and the manufacturer often is of the opinion, privately of course, that the purchaser is unreasonable because he cannot understand how difficult it is to produce sound forgings, once the dies are made.

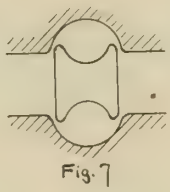
This disturbing situation is due to a lack of knowledge of the principles underlying the flow of metal in the plastic condition. Scientific research on the subject has not been linked up with the practical applications. The individual die makers have accumulated through experience an empirical knowledge. Every set of drop forge dies is largely the expression of an individual opinion as to the flow of plastic metal. Feeling that it is advantageous sometimes to study the reverse side, the accompanying set of photographs is exhibited to illustrate how metal did not flow in the manner originally planned.

Fig. 1 is a representation of a mechanic's square. That part marked A is the forging under discussion. The piece is forged double as shown in Fig. 2. There are at least two reasons for arranging to forge double in this manner: The rate of production is increased; and there is less weight of metal involved in the manufacture of two forgings by this arrangement, than would be if the two forgings were made singly. The flash or excess metal surrounding the outside of the forging is trimmed away and excess metal in the center is punched out, which leaves two forgings supposedly ready to machine for use.

At this stage of manufacture, the forgings are inspected, and during the production of the first few dozens, certain defects called "laps" and "cold shuts" were discovered, the causes and elimination of which constitute the basis of this paper. Low carbon steel 1½ x ½-inch is used as raw material. As originally made, the first operation consisted of redistributing the metal from the uniform section shown in Fig. 4, to that shown in Fig. 5. It will be observed in Fig. 5 that there is a mass or bunch of metal at A and B corresponding approximately to the positions that the bosses will occupy in the forging.

There are very substantial reasons for this preliminary distribution of metal.





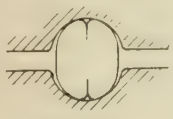


Fig. 4

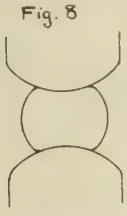
Fig. 5

Fig. 6

Fig. 7

Fig. 8



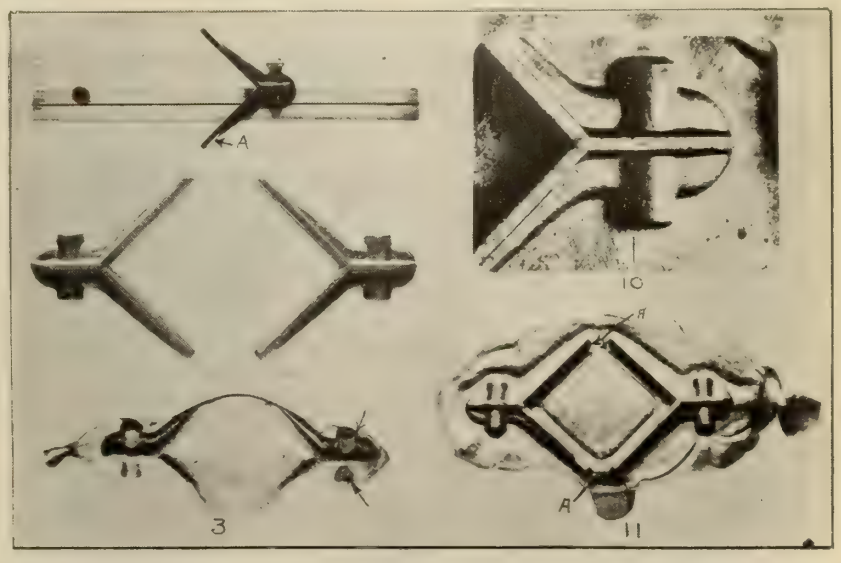


Fig. 9

Fig. 4.—A specimen of the stock used in producing the drop forged part. Fig. 5.—The uniform section of Fig. 4 is redistributed as shown, metal being massed at A and B at the approximate positions the bosses will occupy. Fig. 6.—The section of the partially formed forging as it comes from the first or "edger" operation. Fig. 7—For the second or "rough blank" operation, the piece is given a quarter turn. Fig. 8.—The lips of the cup-like section shown in Fig. 7 are lapped over by the pressure of the dies. A photograph of this operation is shown in Fig. 3. Fig. 9.—To eliminate the lapping effect, the edger may be rounded off somewhat as shown.

First, the productive life of the die blocks is prolonged by removing from the impressions the burden of this mass movement of metal. Second, by distributing the metal in masses to the approximate position required by the impressions in the dies, the formation of a true, sound forging is promoted. Fig. 3 shows the next forging step. It will be observed that this operation is an extension of the preceding operation. The original uniform section of the bar has now became a non-uniform section in which the metal has been distributed as masses into positions from which the forging impression can work or mold these masses into the desired finished shape. Particular attention is called to the boss indicated by the arrow. The formation of a forging defect, known as a "lap" is in progress.

The section of the partially formed forging as it comes from the first or "edger" operation is something like Fig. 6. When placed under the dies for the second or "rough blank" operation, it is given a quarter turn so that the cup shape faces the impression, Fig 7. The action of the dies upon the lips of the cup-like section is to lap them over somewhat as shown in Fig. 8, and it was the photographic representation of this action that was illustrated upon Fig. 3.

In order to eliminate this lap, it is necessary to modify the impression which changes the shape of the bar stock. Because this impression is sunk in the edge of the dies, both the operation and the impression, are referred to as the edger. It is clear enough that the desired redistribution of metal must be accomplished without the formation of the cup shape section of Fig 6. The

Top left.—Photograph of a mechanic's square, the portion marked A being the part of the forging under discussion. Left centre.—It has been found desirable to forge the piece double in the die as shown in this illustration. Fig. 3.—The third step in the forging operation, the arrows indicating the formation of the boss. Fig. 10.—A close up of the laps formed as shown in Fig. 8. Fig. 11.—After trimming, the forging was found to be split at the flash line as indicated by A.

edger may be rounded off somewhat, forming a section somewhat resembling Fig. 9, and this latter section will be found to operate under the rough blank impressions without the formation of a forging defect.

As a matter of fact, these laps were eliminated by omitting the use of the edgers. It was found after making the first dozen forgings, that the bar stock could be placed between the "breakdown" impressions, and produce the shape shown in Fig. 3, without the necessity for any previous preparation of stock, and without the formation of any laps. Fig. 10 is a close up of the laps just described. The rough blank shown in Fig. 3 is transferred to the finishing impressions, and emerges in the form shown in Fig. 11. This forging is ready to have the flash trimmed off and the center punched out.

Another interesting and at the same time instructive type of defect appeared at points A, Fig. 11. After trimming, the forging was found to be split at the flash line. Defects of this nature are common with piped stock, but an extended examination of the raw material demonstrated that the bar stock was sound and homogeneous. Figs. 12 and 13 show a magnified view of the metal in the vicinity of the split. The heavy black streak is iron oxide. It was noticed that this split was just above the flash line instead of in the center of the flash line as would be expected if the defect were due to the material itself.

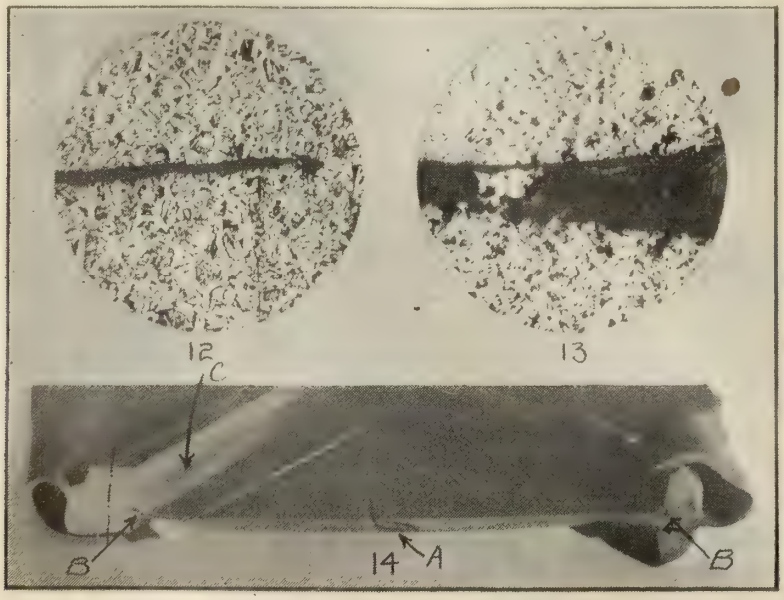

Fig. 14 shows a section of the forging that explains the formation of the defect. Any section of the blank must contain a greater area than the corresponding section of the finished piece. The forging operation consists of forcing out the excess metal while forcing the required metal into the shape contained by the impressions. As a direct result, this excess metal must flow sideways into the flash, that is, the excess will flow toward the outside, and toward the inside of the forging.

The laps in the center at A Fig. 14 illustrate waves of undulations of excess metal that traveled toward the center under the effect of each blow of the hammer, where they were folded over and compressed. Now, when this central web of metal is compressed by the blows of the hammer, the metal has no opportunity to flow elsewhere than to the outside and in so doing must pass through the arms of the forging. The effect of a flow such as just described is to fold the surface into the forging proper. This condition is shown by the black spots just above and below the flash on the right-side of the forging in Fig. 14, and also by the black streak in the left side. When the excess metal is trimmed off, the forgings will show splits or separations of metal at B, just above the flash line.

Several methods are used for removing the conditions which promote the formation of these defects and all are based upon the principle of providing a central web may be forged undersize may flow. For instance, the center can be punched out, or the thickness of the central web may me forged undersize previous to finish forging, or the bosses in the finish impression may be hollowed out.

Fig. 14 also illustrates one more forging defect, known as "mismatching." Referring to the arm on the left, it is obvious that the lower or bottom part of the forging is not symmetrical with the upper or top portion. A defect of this character is due to the upper and lower die blocks being slightly out of alignment. This photograph also demonstrates that the upper die impression shaved the edge of the blank, and formed the lap which is so clearly evident. While the lap was being folded over and pressed down, the metal in the central web may be forged undersize side and the inner surface of the lap and the upper surface of the web were pushed into the interior of the forging as indicated by the black streak at B.

The first forging produced after a hammer set up is carefully examined for forging defects, and adjustments or alterations are made to overcome the objectionable features. By carefully checking up each forging during this period of adjustment, the dies are finally brought into a condition such that a continuous run of perfect forgings may be produced.

Figs. 12 and 13.—A magnified view of the metal in the vicinity of the split shown in Fig. 11. X 100. The heavy black line is iron oxide. Fig. 14.—A section of the forging which explains the formation of the split defect. The illustration is about twice actual size.

HOW EXECUTIVES CAN SHOW A STEADY PROFIT

(Continued from page 39)

"Ordinarily business is conceived as starting with a manufacturing process and ending with a consumer. If that consumer does not want to buy what you have to sell him and has not the money to buy it, then the manufacturer blames the consumer and says that business is bad, and thus, hitching the cart before the horse, he goes on his way lamenting.

"There is no use waiting around for business to improve. If a man wants to perform his function, he must get his price down to what the people will pay. There is always, no matter what the condition, a price that the people can and will pay for a necessity, and always, if the will is there, that price can be met.

"It cannot be met by lowering quality or by short-sighted economy, which results only in a dissatisfied working force. It cannot be met by fussing and buzzing around. It can be met only by increasing the efficiency of production and, viewed in this fashion, each business depression, so-called, ought to be regarded as a challenge to the brains of the business communities."

GRINDING MACHINES

(Continued from page 48)

cuts minimizes spring away or gouging action of the wheel and draws out the surface uniformly.

3.—A single control lever controls all table motions. Pulling the lever toward the operator runs the table back to its station where it remains while size plugs are being used.

4.—A foot pedal stops and starts the work. 5.—Heavy construction minimizes distortion and vibration, and allows accurate positioning in spindle feeding. 6.—Feed index mechanism is located by feel as well as by sight, allowing the operator to watch his work.

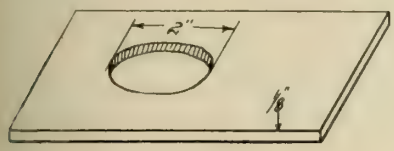
7.—The diamond holder fixture swings out of the way, but can be instantly located at previous position on the table by a single motion. A water supply is provided for cooling the diamond. 8.—Spindles are of the unit type and exchanged as fast as a man can slide one out and put in another. 9.—The machine is self-contained except for a portable water tank which is made separate for quick cleaning. 10.—Engineering service is maintained and estimates are guaranteed as a performance on any particular job where all data with regard to fixtures, materials, etc., are submitted. The Canadian factory at Galt, is handling this machine in Canada.

Practical Ideas for Shop Executives

CAPACITY OF A PUNCH PRESS

By I. N. B.

To determine the rating of a punch press square the diameter of the crank pin and multiply by 3.5. This will give the capacity in tons. Suppose the diameter of crank pin is 3 in. Then:

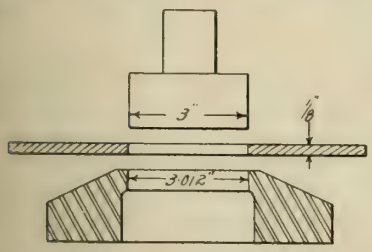


3 x 3 x 35 = 31.5 tons.

The above rule is used by one of the large press manufacturers in the States, and applies to presses of limited stroke only. This may be used to advantage when giving work to different presses.

To find the pressure in tone required to punch circular holes in sheet steel, multiply the diameter of the hole by the thickness of sheet and by 90.

Example:—To punch a 2 in. hole in ⅛ in. stock.



2 x .125 x 90=22.5 tons.

For brass, use the factor 75.

In calculating the pressure required for irregular holes take 1-3 the total length of outline and multiply by the thickness and the factor. Example: 2 in. square hole in ⅛ in. steel sheet.

1-3 of 8 x .125 x 90=29.92 tons.

It is understood that these rules are only approximate, as the pressure depends upon the composition of the metal, the shear given the cutting edges, and the clearance between the punch and die. Practice has demonstrated the following clearances to be about right: for soft steel, thickness of stock divided by 20; for medium hard divide by 16; hard rolled stock divide by 14. Example: clearance when punching ⅛ in. soft steel would be .125÷20=.006 in.

FIVE SIMPLE JIGS

By J. H. M.

In the making of parts for an "Ironer," several jigs of varied character, are necessary. The Sumbling Machinery Co., Toronto, make a varied line of ironers, and the illustration shows a few of the jigs used on this work. Take for example, A.

Here we have a jig for drilling the bearing link. There is a right and left hand casting for these links, the boss being on the opposite side as the case may be. The one jig does for both right and left styles. Adjustable screws with lock nuts provide the ganging points, and a ⅞ in. hole is drilled at (a), a 1 in. hole at (b), while the two bushings (c) and (d) drill a ½ in. hole in the right or left hand bosses, depending upon which is in the jig. A swinging support, not shown on photo, takes the thrust of the 1 in. hole while being drilled.

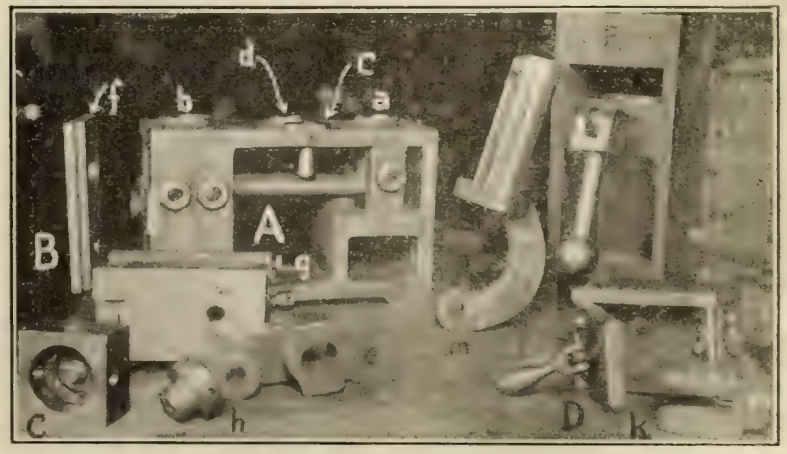
The jig B is used to drill the pressure link shown at (e) and a 15/16 in. and ½ in. hole are drilled at this operation. The method of holding down the bushing plate (f) is worthy of attention. The spring clip (g) fits into a small nick in the plate (f) which holds it sufficiently tight for this style of work. It is quick and effective for light work of this nature.

The jig C drills four ¼ in. holes, the piece being shown at (h). It is placed on the centre stud shown, which is threaded, and after drilling each hole, the jig body is turned over 90 degrees.

We next come to the jig D. This is used to drill the double eye hook shown at (k). This piece is drilled at the side with two ½ in. holes, and the end of boss is drilled for ½ in. tap.

The last jig shown in this group, E, is used for drilling the spring cage shown at (m). A ½ in. hole is drilled at end of boss, and a 33/64 at the other end. An eccentric form of clamp is used. These jigs, in principle, are applicable to any shop, and may contain some useful hints as they are simple in character, yet effective in their work.

MEETING EMERGENCIES



On one occasion our punch press was busy when we needed a quantity of leather washers in a hurry. Having the punch and die on hand, we rigged them up on a drill press equipped with lever feed. The die was secured to table and the latter locked in position. The operation was successfully performed by a girl.

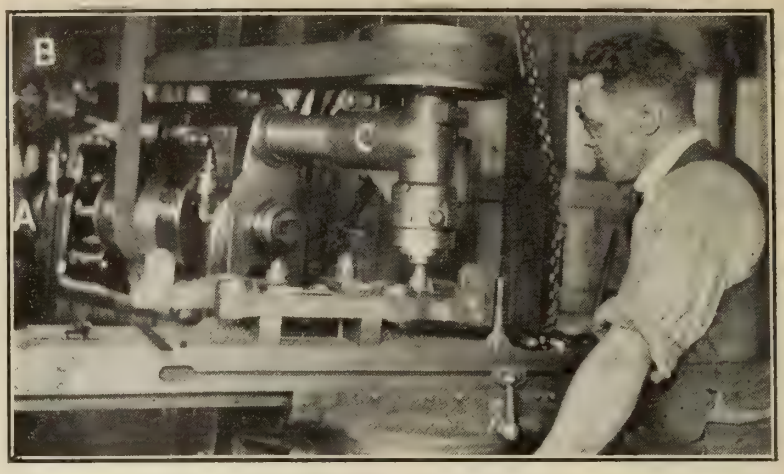
At another time we were in need of some special bronze wire, No. 12 gauge. We had only No. 10 gauge in stock, so to avoid delay in getting the small quantity required, we made a drawplate with four holes in it, with a reduction in each case of about .005 in. The drawplate was held in the lathe chuck, which, of course, was stationary, and the end of the wire passed through the plate in the usual way and gripped in the tool post. The carriage was then moved along the bed to the limit of its travel, the wire released and the operation repeated until the required amount was obtained.

To overcome the constant slip of a 40 in. pulley, we replaced the split wooden bush with one of cast iron, through which passed a number of ⅝ in. set screws, impressions being made in the shaft to receive the points of the screws. This ended further trouble.

HARDENING HIGH-SPEED CUTTERS

A good method for hardening high-speed form cutters is to use a muffle gas or oil furnace for heating the cutter. The cutter should first be preheated to a temperature of from 1600 to 1700 deg. F., and then placed in a muffle furnace and heated to a temperature of 2200 deg. F. As soon as the cutting edges have attained the latter temperature, the cutter should be removed from the furnace immediately and quenched.

Five simple jigs for "ironer" parts.



SIMPLE VERTICAL ATTACHMENT

By J. H. M.

For the shop which cannot afford the price of a regular vertical milling attachment, the idea shown in the photograph will be found to be well worth while. The device depicted was made at the Sumbling Machinery Co., Toronto, and briefly here are the necessary parts.

A pulley was placed on the rear end of spindle as shown at A. Two smaller pulleys, attached to a bracket were fastened to the frame of miller at B, being easily detached when not required, and a body portion C was bored out to fit on the over-arm of machine.

The spindle construction was of the usual design, ball thrust collars being located at the lower end. A pulley was fastened at top, this receiving its power from the spindle by means of the belt shown. The attachment has proved very useful for varied work, and could well be adopted by other plants.

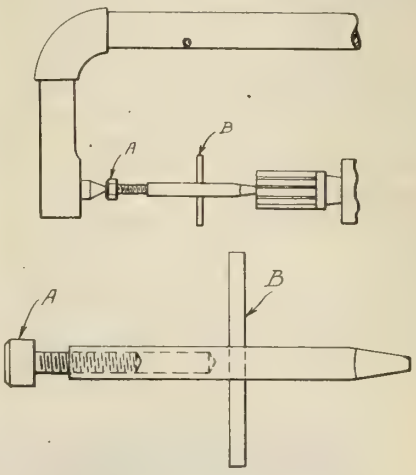
Vertical Milling Attachment.

SCLEROSCOPE TEST

By J. Davies

I am much obliged to Mr. Brigham for his answer to my questions regarding the testing of balls with a scleroscope. I read his reply with great interest, but I do not think the way the balls are held, and the glancing blow, entirely explains the curious results. Since reading Mr. Brigham's reply I made another test.

I got a 1¼ in. ball which scleroscoped 95. Then I got a ⅜ in. ball which registered 42 under exactly the same conditions, great care being taken to get the blow exactly in the centre. The makers claim that these balls are of the same commercial hardness. An interesting fact is that the maker of these balls states that a 7/16 in. ball registers the same whether hard or soft.



In reference to cutting the threads on the jaws of a universal chuck, I had in mind what would be the best method in an ordinary machine shop where they carried out their own repairs and had no special machines. How is the relieving done for the travel of the jaws? That is the most important part of the question.

TEMPERING OIL SPRINGS

Small coil springs may be tempered in a furnace burning wood by being first exposed to the flame, and then quenched in a mixture of 10 quarts of rosin, 12 quarts of tallow and a barrel of fish oil. More tallow should be added if the springs break after tempering, but if the break is only due to brittleness and not to hardness, a 6 in. diameter ball of yellow beeswax should be added The springs can be drawn to a reddish purple by being laid on a frame with horizontal radial arms mounted on a vertical rod. Held on this star-shaped contrivance, they should be lowered into a crucible of molten lead until drawn to the color desired.

REMOVING LIGHT SCREWS

Screws, used for holding shell mills on milling machine arbors, very often work themselves so tight that it is impossible to remove them with an ordinary screw driver and other drastic methods, such as a hammer and punch are brought into play, with results hardly beneficial to either the screw or the arbor. The tool shown in the drawing overcomes the objection to a hand operated screw driver, by compelling the blade to keep in the screw slot while turning. The back end of the tool is tapped out for a screw A the same pitch as the screws used on the arbors, the head of this screw being centre drilled. A hole drilled through the centre takes

Removing light screws

a piece of drill rod to act as a handle B to turn the screw driver. When it is desired to remove a stubborn screw the overarm support is brought down as shown and pushed snugly into the centre hole on the screw head, after which the nut binding the support is tightened. With a wrench on the screw A it can be adjusted to push the blade of the driver further into the slot if required. Most screws will yield to a gradual push on the handle B and the most stubborn to a light tap with a hammer. A wrench should be held on the screw A to prevent it from turning, as the screw is backed out of the arbor.

BABBITT FOR GRINDER SHAFTS

By D. A. Hampson

Like other shops, ours found that one of the ever recurring repair jobs was rebabbitting grinder spindles. In spite of educational campaigns, workmen will wear emery wheels out of round and they will monkey with the bearings, one time getting the latter so tight that the babbitt cuts and the next leaving the caps so loose that the boiler shop music starts—these little "attentions" coupled with the nature of the work generally makes the grinder a hard machine to keep in shape. Some form of adjustable bearing is necessary. The babbitt bearing, with its anti-friction properties, answers about as well as anything we know. Shops usually carry two or three grades of babbitt for general repair work—say, genuine babbitt for engines and high speed shafts, No. 4 metal for cheap work and filling purposes, and a grade between. And so when the grinder needs new bearings, one of these is selected. In the end, one does about as well as the other.

We had made some feeble attempts to get a more durable grade of babbitt for grinder work but we found the salesmen invariably passed off their most expensive metal on us without regard (or knowledge) of its qualities. Finally we hit upon a good idea. We went to the local street railway company and asked what they used in their motor case bearings. Now if there is anything that gets a pounding similar to that on a grinder it is these street railway bearings—and, knowing that trolley roads operate on a strictly utility basis, our conclusion was that they would have a durable bearing metal. We got the metal and it has proven better than we expected, so much so that we have put it in other bearings since. It is a bearing material made to stand heavier work than on grinders together with a higher surface speed of the journal. Which goes to show that it is possible for the progressive shop man to learn from other fields, even from the rather despised car barn practice.

New Things in Shop Equipment

HELICAL-FLUTE EXPANSION HAND REAMER

A helical flute expansion reamer in which the cutting action of the teeth is said to be such that all clatter is eliminated has recently been placed on the market. True and accurately sized holes can be produced. The reamer is made in various sizes by the Millersburg Reamer and Tool Co. of Millersburg, Pa.

MOTOR DRIVEN DISC GRINDER

A new disc grinder designed for sanding pieces such as segments, angles, core prints, circular and taper work, etc., has just been placed on the market. The machine is portable, of rigid construction, and fitted with exhaust system for dust deposit. The disc is of steel, 13 in. diameter and spindle has a speed of 1,725 R.P.M. Table is of cast iron, 9¼ in. by 21 in., and may be tilted to an angle of 45 deg.; 25 deg. by means of handwheel. Graduated index permits accurate setting. It is also provided with circle segments and duplicating gauge. Motor is direct connected to disc shaft and runs on ball bearings. The machine is made by the Oliver Machinery Co., Grand Rapids, Mich.

SPECIAL DRILL STAND

To accommodate portable electric drills so that they may be used as bench machines there has recently been placed on the market a special stand. The unit to which the drill is attached may be clamped in various positions along a vertical bar, according to the height of the work. The drill is then raised and lowered for the drilling operation through the manipulation of a long lever. The motion in this case being all in the unit, and the clamps remain rigidly attached to the vertical bar. The stand will accommodate the ⅜ and ½ inch drills manufactured by the same firm. The weight of the stand without the drill is 68 lb. The stand is manufactured by the United States Electrical Tool Co., of Cincinnati, Ohio.

NEW LIFT TRUCK PLATFORM

A platform which may be adapted for use with either hand or power lift trucks is now being manufactured. The platform consists of wood planks to the bottom of which are bolted two steel skids. Riveted to these skids are four steel brackets in each of which a wooden leg block is bolted to support the platform. The blocks are renewable and can be replaced as they become worn, and they also can be made of different heights to suit the truck used. The skids flare outward at each end which gives easy access to the truck. No projecting rivets, nuts or bolt heads which might come in contact with the truck are permitted in the construction of the platform. The platform is manufactured by the Standard Pressed Steel Co. of Jenkintown, Pa.

STAY BOLT THREADING MACHINE

A machine that has for its object the saving of time in the threading of staybolts has just been placed on the market. The makers have used their standard turret machine as a basis of construction for the staybolt threads, using a special attachment to carry the die heads. The regular slide may be used for ordinary work. The forward die is specially designed so that a large opening of the chasers permits of insertion of the button head before gripping in the chuck. A steady rest is provided between the two die heads. Die heads are operated automatically by means of cams on rear bar, these cams controlling the action of the chaser to suit the thread being cut. The machine is manufactured by C. H. Breaker, Indianapolis, Ind.

MOTOR DRIVEN HACK SAW

A hack-saw which is electrically driven by a motor which, together with its control switch, is built into the machine, so as to be out of the way and at the same time well protected, has recently been marketed. The slide of the hack saw is above the blade for the purpose of keeping it free from chips and dirt. The vise swivels and is graduated to facilitate setting for angular cuts. The stroke of the machine is adjustable from 5 to 7 inches. Two speeds, one of 45 and the other of 90 strokes per minute, are provided. A sixteen-inch blade is used, with gravity feed. An automatic stop shuts off the motor at the end of a cut. The motor is mounted on ball bearings and can be furnished for all standard circuits. An oil pump can be furnished if required. The machine weighs only 450 pounds and can be quite easily mounted on a platform on wheels for portable work. The Louisville Electric Mfg. Co., Louisville, Ky., are the manufacturers.

PORTABLE WELDING OUTFIT

An oxy-acetylene welding outfit which is also provided with a tube that adapts the apparatus for burning carbon from automobile and marine engine cylinders, has been recently placed on the market. It has been designed for use in machine shops and service garages. In addition to the carbon burning tube the equipment consists of a welding torch, five welding tips, single gauge oxygen and acetylene regulators, oxygen and acetylene hose, and several other necessary parts. The whole outfit is contained in a fibre case. The welding torch is 16 inches long, operating on the balanced pressure principle. Mixing takes place in the tip. The seats of the regulators close with the pressure rather than against it. The carbon-burning tube fits into the torch head similarly to a welding tip. It may be convienently attached and replaced as it becomes worn out. The outfit is manufactured by the Alexander Milburn Co. of Baltimore, Md.

BENCH AND FLOOR TYPE ELECTRIC GRINDER

An electric driven grinder having ½ h.p. motor, and designed to do duty as a bench machine, but which can also be fitted with a cast iron pedestal for floor work, has recently been placed on the market. The grinder is fitted with double-row ball bearings and a motor suitable for operating on either 110 or 220 volt circuits, single, two or three phase, alternating current. The grinding wheels are 8 inches diameter, ¾ inch face, with ⅝ in. hole. The wheels are extended well away from the motor casing, to permit the grinding of comparatively long or irregular-shaped pieces. One coarse and one fine wheel are regularly supplied. The switch is located on the top and centre of the motor housing and is of the make-and-break design. Ten feet of reinforced cord is regularly supplied with a plug. The bench type of machine weighs 110 pounds and the floor pedestal equipped machine weighs 225 pounds. The machine is manufactured by the Standard Electric Tool Co. of Cincinnati, Ohio.

RATCHET WRENCH SET

A set of ten wrench sockets which accommodate all sizes of nuts from 7/16 in. to 1 in. inclusive, adjustable T-handle, reversible ratchet, universal joint, extension piece, two screw drivers and a box wrench, all packed neatly in a well finished wooden cabinet, has recently been placed on the market. The wrench sockets are manufactured by a special process, which, it is claimed, gives the metal greater density and strength. The sockets are provided with hexagonal heads over which the wrench members fit when they are in use. The T-handle has an adjustable cross bar which can be used in a central position or adjusted to obtain the maximum leverage. The ratchet may be set for use either right or left hand. The extension piece is used between the T-handle and a socket, when required to get at nuts in inaccessible places. The Eastern Machine Screw Corporation of New Haven, Conn., are the manufacturers. The outfit is marketed under the trade name of "H & G."

STRAIGHTENING PRESS

A straightening press, intended for handling large quantities of parts without removing same from between centres, has recently been designed and placed on the market. A round bar, on which centre brackets are mounted, is fitted to a sliding head provided with a roller bearing. The bar can be moved freely to the right or the left to permit the straightening or bending of work at any point along its length. The sliding head unit is pivoted to the frame of the press, and held in a horizontal position by a vertical shaft equipped with a compression spring on both sides. The head has an up and down movement. An adjustable stop screw permits of set-ups of work that ordinarily would not clear the blocks. The press hand wheel is graduated into twenty-five equal spaces. By turning it through one space a movement of one one-thousandth part of an inch is obtained. The amount that the part to be straightened is out of truth can be read in thousandths from a dial indicator supplied with the machine ,and used on the work located between the centres. The press is used largely on internal combustion engine crankshafts and many similar parts. The machine has been developed by the P. A. Geier Co., of Cleveland, Ohio.

SAFETY TAP AND DRILL CHUCK

A safety chuck for straight shank drills and taps has just been offered to the trade. The chuck has a safety device intended to prevent small drills, taps, reamers, counterbores, etc., from breaking, it is intended for hand feed only. The safety device is a friction and a soft steel pin that shears when the cutting tool is overloaded. The drill or tool is held in a hardened collet by a Bristo hollow safety set screw which positions on a flat in the tool shank. A soft steel driving pin goe through the collet and a hardened male friction. The friction is adjusted by hand with a knurled nut which is on the outside of the chuck body. When the friction is too tight and the tool sticks, the pin shears before the tool breaks. The female part of the friction is keyed to the body, and the nut bears only on it, this prevents tightening and loosening when the tools are run forward or backwards. A ball race takes the end thrust. There are three sizes of pin holes in the standard collet, the smaller holes are for high speed drills which are weaker than carbon drills. For chucks that are used on one job only, collets with one pin hole are furnished or the other holes are plugged. The pins are held in place by a spring plunger. These drill chucks are made by the Save All Tool Co., Waltham, Mass.

FLEXIBLE SHAFT COUPLING

A flexible shaft coupling which has a free turning motion around hardened steel pins and a sliding motion in a tongue and groove connection is now being marketed. Two styles of this design of coupling are made. A uniform velocity ratio, between the shafts connected, is maintained, irrespective of the amount of angular or lateral misalignment. The design also permits of ample end float essential when coupling up alternating current motors. In such installations the two sliding members slide in and out as occasion demands. One design requires two hubs to be keyed on the ends of the shafts to be coupled. Two rings on the hubs engage each other by means of a tongue and groove construction, and bearing pins driven transversely into each hub. The other design is similar except that the pins are driven directly into the shaft ends, the hubs being omitted. The pin in one shaft engages the slotted ring mounted on the other shaft end. The component parts of the couplings are made of machine steel and are heat treated. It is claimed that with slight changes in the construction a positive transmission can be had between shafts set at any angle up to 90 degrees. The coupling is manufactured by C. H. Breaker, Indianapolis, Ind., and marketed under the trade name of Bartlett, the name of the inventor.

TUBE WELDING MACHINE

A new type of tube welding machine designed for the quantity production of large diameter thin gauge tubing has been recently brought out. This machine is especially adapted for use in tube manufacturing plants where it will be set up and used for long runs on one size tubing. There are two sets of rolls, one for feeding and one for welding. The drive is by belt to a three step cone pulley from which the drive to the rolls through the gearing, is taken off. The welding rolls have annular depressions feed rolls, in front, are adjustable. The welding rolls have annualar depressions on top to receive cooling water and a water circulating system can be provided if necessary.

The welding torch is made by the manufacturers of the machine, and is of the multiple-jet, water-cooled type. Both the tip and the barrel of the torch are cooled by circulating water, to maintain the conditions necessary for successful continuous welding. The torch holder permits of vertical and horizontal adjustments of the torch, and the varying of the angle at which the tip is presented to the seam to be welded.

The maximum capacity of the machine is for tubing 6 in. in diameter made from No. 10 gauge. Although designed and built for quantity production of one size and gauge of tubing, the machine can be set up for any diameter and gauge of tubing, within its capacity, by employing rolls grooved to suit the desired tube diameter. All rolls whether for large or small diameter tubes, are of the same size over all as the normal centre distance of the rolls and their mating gears must be maintained. The Davis-Bournonville Co., of Jersey City, N.J., have developed, and are marketing, the machine.

BALL BURNISHING BARREL

This new type of burnishing barrel differs from older types in the fact that it contains fixtures for holding the work during the burnishing operation. The usual method is to let the work tumble freely in the balls, soap and water. To some extent this caused the scratching of the work. The new design of barrel has an eight sided periphery, each side of which is fitted with a hand hole, hinged cover and lid. These eight sides are located between two circular discs which carry the gudgeon pins or shafts on which the barrel revolves. Each one of the eight covers has bevelled edges which fit into seats machined to suit, in the frame of the barrel. A packing ring makes them absolutely tight. Pressure is maintained between the surfaces by means of a flat spring located on the backs of the covers and which acts as a handle when removing the cover. The fixtures for handling the work are located on the inside of the lids which fit inside the covers. Several sets of interchangeable lids can be procured for one barrel which permits of extra pieces being placed in the fixtures on the inside of the lids while the burnishing process is going on. With work that is to be plated, plating operations can be carried on without removing the work from the lid, and then the lids can be placed in the barrel and the final burnishing can be accomplished without removing the work. The machine is belt driven, a fast and loose pulley with gear reduction being furnished. The barrel is manufactured by the Abbott Ball Co., Elmwood, Hartford, Conn.

BOOK REVIEWS

The Norton Co., Worcester, Mass., is circulating a 28 page illustrated booklet in which metal polishing is described. The booklet goes into detail as to the materials to be used in this work, and the various kinds of operations to which the different materials are best adapted. They have also published a booklet in which factors affecting grinding wheel selections are given. According to the booklet, grinding is such an important part in modern manufacturing processes that an understanding of the factors involved in selecting a grinding wheel for a certain job is extremely helpful to the shop superintendent, mechanical engineer, foreman and workman. The booklet points out just what factors have to be considered and the relative importance of each. Anyone desiring copies of these can secure them from the Canadian office situated at Hamilton, Ont.

The Ingersoll-Rand Co., of Sherbrooke, Que., are issuing a revised service information sheet on "General Instructions on the Use and Care of 'Little David' Air Tools."

The Steel Trough and Machine Co., of Tweed, Ont., have just issued a new catalogue, No. 32, covering their complete line of heavy sheet steel goods. It is well illustrated with valuable data.

Workers Want Longer Working Day

TO WEAKEN British competition in the world's markets, Germany some 30 years ago began propaganda in England, particularly in the machinery field, for shorter hours and reduced output. The campaign was pretty successful. It developed into a nation-wide strike of machinists in 1897. The machinists lost, but the propaganda has been carried on since, there and in Canada.

While the Germans were urging these means of increasing costs of British goods they showed no signs of carrying out this same policy in their own country until the defeat brought Socialists temporarily into power when in some parts and industries of Germany they adopted the eight-hour day. Latest news from there shows that the workers themselves, as a result of experience, are wondering whether it is going to pay and their shrewdest leaders are now asking for a return to the longer day. An interesting review of the situation appears in another column.

Be Sure—Then Go Ahead

"YOU SIMPLY cannot afford to pass up this opportunity," remarked a salesman recently to a prospect, and upon being asked to explain himself in detail, went on to propound reasons why his proposition should be accepted. As it happened he was an advertising salesman, and while his arguments sounded all right to himself, he did not realize how little impression they were making on his prospect who was a specialist in a certain type of business machine. The salesman was trying to convince the specialist that he should sell his equipment to coal mines, and, of course, that he was offering him the best and only medium for such a purpose. Feeling that he had covered the situation quite thoroughly the salesman paused, but was greeted with this question:

"Have you ever been down in a coal mine?"

"Why, no," was the reply in a somewhat astonished tone.

"Because if you had ever visited a coal field you would realize immediately that the arguments you have been giving me do not hold water. I have been at the mines for the past few months trying to sell the very equipment you claim I can dispose of through your medium," continued the specialist, "and I find that their methods of working do not lend themselves to such machines."

Before the salesman left he heard further enlightening truths, but while this happened to an advertising representative, there is a lesson in it for every salesman and manufacturer, irrespective of the product he sells or produces. It is this:

Study your product thoroughly. If you are making the goods ask yourself if they are being manufactured and packed in the best way possible to sell to the trade. If you are selling the product, do not attempt to convince a prospect before you know the details of his business or requirements. Get a walk through his plant if you can, and failing this, discover through other channels, the best manner of approach. Do not step in blindly and tell him he cannot afford to pass up your proposition, for ten chances to one he will make you prove your rather loosely worded statement.

How Much?

THE NEWS from the building fields is discouraging. Though 90 per cent. of all unemployment in Canada is in these trades; though employment in the building industry shows a shrinkage of 42 per cent. against a general shrinking in all industries of only 12 per cent.; though the 1922 outlook for building is for at least 25 per cent. less than last year; labor agitators are still urging and getting the workers to hold out for war-time hourly wages. In some trades, like carpenters, while there is a nominal scale of 90c per hour the real wage is 80c and many are working for less.

Manufacturers generally will support the Building Trades Unions in getting the highest wages the industry will bear —the highest price the public will pay for homes and larger buildings. If workers can get in 300 days at the hourly war wages it would mean busy factories. But manufacturers, judging from experience, feel very sure that the public will not again pay war prices for building, etc. They have dropped their own prices over 50 per cent. in some cases—and every week shows a further decline—in an effort to get orders, but still the demand grows less and more plants shut down.

Manufacturers advise labor leaders to take their mind off the war scales long enough to study general conditions. If they give assurance of steady employment for 1922 and lay solid foundations for succeeding years, then they would be justified in holding out for the present high rates. If they do not, they should quickly reduce and keep on reducing them, as the manufacturers have done with commodities, until they can find the basis on which buyers will come in freely. Then they can increase as the demand warrants. There has been a heavy reduction in salaried incomes all through Canada. It is strenuous conditions not happy ideals we are facing to-day. Some income is better than no income and public charity.

The records for automobile fatalities for Toronto for the eleven months of 1921, as compiled by the Safety League, show a total of 45 such deaths on the streets of Toronto. This figure is a noticeable improvement over 1920 when there were 64. which means a reduction of 30% in fatalities, in spite of an increase of thousands of motor cars registered in 1921. In the months of January to November inclusive, 1919, there were 47 automobile deaths on the streets of Toronto, so 1921 shows a slight improvement there too.

Steel Business Is Picking Up Gradually

No Important Price Changes—Open Weather Helping Steel Trade—Small Tools and Supplies Are Fairly Active—Machine Tools Only Fair—Scrap and Non-Ferrous Metals Weak

STEEL PRODUCTION SHOWS GOOD INCREASE

THE AMOUNT of business being closed on the Canadian steel market can safely be said to range from 50 to 55 per cent. normal, with a slight increase for the better every week. There have been no important price changes so far this week.

The steel market in the States shows an increase in demand, and practically all orders closed are for very prompt shipment. Steel production is now nearly three times the rate of last July, but of course general business is not three times as active. Pig iron, basic, is selling at 25 cents less per ton than last week, this price being on large orders. Sheets are steady, hoops are lower, and the demand for pig iron is somewhat heavier.

Manufacturers are showing more interest in the market these days and some good orders have been secured. The railways have not yet come into the limelight, but are buying only in a small way. One good feature in all markets is the general nature of the demand. The size of the orders is not very large, but is scattered over a variety of industries, this bringing the total up to good proportions. This is a healthy condition, and once manufacturing plants and foundries widen their activities, a good volume of orders for iron, steel, and general metals should result.

Machine tools are spotty; some dealers are securing fairly good business, while others are extremely dull. Aggressive salesmanship is responsible for orders being closed, and those content to sit around are securing no business.

Pig iron in Canada remains at the same level as last week, and the demand is very light. Where large orders are on tap, the regular price is shaded, some sales being closed as low as $26.60, although the average consumer in Toronto may be asked $27.15. The price in other localities varies according to the distance from source of supply.

Shading of prices on many steel goods continues, especially if the orders are large. Generally speaking, however, iron and steel bars are selling at $2.75, and band steel at $3.25. These are Toronto quotations.

Small tools and supplies are holding their own in the Toronto field, but a little added improvement is noted around Montreal. The month just closed will show up better than January, and prices in these lines continue to remain firm.

Scrap and non-ferrous metal prices remain weak, and there is practically no demand. Conditions look dull for some time to come, and no noticeable improvement can be looked for until foundries become more active.

Toronto

March 1.

THE MONTH of February was not so bad as some dealers expected. In fact, when viewed in comparison with January, there was no cause for complaint, as the total about of business closed was better than many anticipated. The small tool and supply market was the best of all sections.

Iron and Steel.—Conditions in the iron and steel market shows an improvement over last week. A few concerns claim they have noticed no added interest, but these are very much in the minority. One dealer mentioned to Canadian Machinery that he secured such a number of enquiries and orders last week, that it took his staff all their time to handle the improved demand. The best feature of all was that this demand was general in character and not confined to merely a few specialized lines.

About a block from this scene of activity, another merchant told Canadian Machinery that he had experienced a rather poor week. In another section of the city a representative of a large steel concern mentioned that the last week was exceptionally good, and that the character of the orders were all that could be desired under present circumstances. The average dealer feels better, and it is the fellow who is content to sit back and wait for business to come to him that is finding the going rather hard. There has been more aggressive salesmanship displayed during the last few months than occurred all during the war period. The chief feature of the increased demand is its wide scope. Usually the orders are for small quantities, being for immediate requirements, but one dealer told Canadian Machinery that the orders he received last week alone, covered thirty branches industry. This is a very healthy sign, and once general business picks up to a greater extent, all iron, steel, and metal markets should benefit. Following are prices on the main iron and steel lines:

Iron bars	2 75
Steel bars	2 75
Reinforcing bars	2 75
Steel hoops	3 75
Tire steel	3 00
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in. base	3 25
Small shapes	3 00

Machine Tools.—Business on this market, while not very brisk, seems to be slightly improving as the year advances. Enquiries still continue numerous, but quite often after a much desired order is about to be closed, a hitch occurs which holds up the prospect for another three or four months. It is a common occurrence for a dealer to keep in touch with a prospect for over a year, always hoping something will break. Shading of prices is still existent, and while this may not appear on the surface, it exists nevertheless. Buyers are having their innings, and in many cases are driving very close bargains.

Small Tools and Supplies.—This branch of the market is holding its own locally. One cannot truthfully say there has been any improvement since last week, but conditions are certainly no worse. In the majority of cases the buying is of the hand to mouth variety, with the result that considerable expense is entailed even in the closing of a small order. There is the sending of the enquiry, the submitting of quotations, placing of order, acknowledgment, etc., all this tending toward expense. One dealer actually put on additional help in his stenograph department in order to type quotations and general answers to enquiries, and yet, boiled down to actual business closed, the total doesn't amount to much.

Luckily, there is a seeming trend toward better things, for one dealer told Canadian Machinery that various firms are now realizing the clerical cost at both ends, and are asking for prices over an extended period. If this movement becomes general it will be good for business all around. Lines such as drills, taps, files, reamers, etc., are in fair demand, and general supplies, as required in mining sections are picking up. In fact several dealers are making their new camp up north at present, as they look for good business from the mining locality.

Pig Iron.—The demand for pig iron remains dull. There has been no change in price. Foundries are still inactive, with little hope of immediate opening. Following is the existing price.

Silicon, 2.25% to 2.75%	27 15

Non-Ferrous Metals.—Prices are weak in all non-ferrous metals, and the demand is very light. There has been no change in Toronto prices, although the Montreal figures are shaded slightly. This has made no effect on local quotations as it only amounts to a quarter of a cent a pound, and Montreal may have secured some metals by a more direct route, thus reducing the freight cost slightly. Following are existing quotations.

Lake copper	17 50
Electric copper	17 25
Castings, copper	17 00
Tin	34 50
Spelter	7 25
Lead	6 75
Antimony	8 00
Aluminum	27 00

Scrap Metals.—Demand is very weak in scrap. Prices have not changed since our last report, and until foundries pick up, no move of importance can be expected. Following are Toronto prices:

Copper, light	8 00
Copper, crucible	10 50
Copper, heavy	10 50
Copper wire	10 50
No. 1 machine composition	8 50
New brass cuttings	6 00
Red brass turnings	6 00
Yellow brass turnings	4 75
Light brass	3 50
Medium brass	4 50
Scrap zinc	4 00
Heavy lead	4 00
Ten lead	3 00
Aluminum	10 00

	Gross
Boiler plate	9 00
Heavy melting steel	12 00
Axles (wrought iron)	20 00
Rails (scrap)	12 00
Malleable Scrap	12 00
No. 1 machine cast iron	19 00
No. 1 machine cast iron	19 00
Pipe, wrought	6 00
Car wheel	18 00
Steel axles	18 00
Mach. shop turnings	6 00
Stove plate	16 00
Cast boring	6 00

Miscellaneous.—Other lines, such as oils, greases, steel pipe, waste, belts, etc., remain in fairly good demand. Prices are unchanged in any of the above mentioned lines, and the majority of business closed is for immediate needs only.

Montreal

March 1

FOR the first time in several weeks a general improvement in the local iron and steel business has been noted. The change for the better is not on a large scale but is certainly of a positive nature. At the same time there are some commodities that have not participated in the improved tone. The improving conditions were not altogether unexpected and are somewhat of a seasonable nature. The waterfront is commencing once more to attract attention. Every spring there is a great deal of repair work, improvements, and renovations in this quarter. The steamers that winter here are being carefully surveyed, previous to starting the work of recommissioning them. All the harbor tugs, the lighters, the unloading plants, and other varied port equipment is due for the spring overhauling. The initial orders that this work naturally necessitates, are commencing to come in, which is, in a measure, responsible for the better tone locally. Then, too, the manufacturing plants are coming into the market for certain lines in a way that is more encouraging. As yet the increase in business is not of large proportions, but is of interest as in many cases it is the first orders for certain materials that have been placed by many firms since New Year. These conditions together with the general spirit of optimism that is usually present in the spring, has impregnated the whole situation with a very satisfactory feeling that better times are coming. There is not present any artificial inflation and a genuine demand for materials for immediate consumption is behind the improvement. It is fully appreciated that the general situation is suggestive of a gradual improvement extending over several months. The railways as yet have not come into the market, except in a small way for supplies and equipment which are required immediately. It is known that the policy of these corporations for some time back, has been one of purchasing from hand-to-mouth. For this reason it is expected that in the near future some nice orders in various lines can be expected.

Steel Market—The call for merchant bars has not improved during the week, although some interesting inquiries of fair size have been received. The structural steel sales have not improved to any great extent. The outlook for this particular department is, however, very promising as the local building program is larger this year than it has been for several years past. The largest improvement in the steel products has been in boiler tubes. The marine interests have placed quite a few nice orders lately and inquiries from various sources are numerous. The demand for plates has been somewhat better. The orders received have been from varied sources for a variety of uses in new and repair work. Sheets have been fairly active since the new year but the volume of business has fallen off, of late. This is due to a belief that prices in the States are due for a drop owing to the weakness in British and European markets. Whether this assumption is right or not, remains to be seen. It is generally conceded that present prices are about as low as can be expected when one considers the present production costs. It was fully expected that orders for rails from the railways would have been placed before this. Up to the present there have been no signs of the looked-for orders. It is generally felt that the requirements of the roads will bring further orders at any time now. Quotations have not materially changed in the last week. Local current figures are as follows:—

Iron bars, base, Montreal	2 75
Steel bars, base, Montreal	2 75
Reinforcing bars, base	2 75
Steel hoops	3 75
Tire steel	3 00
Spring steel	6 00

Pig Iron:—A slight improvement in pig iron has been noted in the last week. In December the demand for pig iron started to fall off gradually and continued until about the middle of January when the dullest period that had been experienced in years was reached. Practically no orders were booked for several weeks. Not until this week, however, was there noted any improvement in the demand. It was thought that the drop in price of two dollars a ton several weeks ago would have stimulated sales, but such was not the case until recently. No large orders have been received, but there have been a very nice number of car-lot orders booked. Some foundries have come into the market for the first time in months. In fact most of the orders being received to-day are from the small foundries who are experiencing a little spurt in business. The larger consumers of pig are still operating at part time and are purchasing only in small lots on the hand-to mouth plan. No change in price has been made, and from present indications no changes are contemplated.

Machine Tools and Supplies:—The movement of machine tools is slow and there is but little to lead one to believe that the demand will be much better for some time to come. Orders to-day are usually for one tool only and but few instances have been reported where a sale of a large tool has been made. Dealers are contenting themselves with keeping their prospects informed on all the various improvements and price reductions. As there is at present a surplus of machine tools in the country, when the present demand for manufactured articles is considered, it is pretty hard to convince a shop man that he is in need of new equipment. One point cannot be concealed, and that is during the present dull period machine tool manufacturers have used their surplus designing and engineering capacity to more fully develop and improve their product. Thus when at some later time manufacturers do come into the market for machine tools, they will have a very fine line of machines ready for them. As before stated, the sale of new tools is small, but there is a fair demand for second-hand tools. A large number of these tools have been on the market for some time past, but they are gradually being absorbed. In spite of their ever decreasing numbers, a fair volume of business is being done every week.

The supply business is still very satisfactory and at the present time is the mainstay of the businesses of several local dealers. There has been a gradual and healthy improvement in this department for some months past. On one or two occasions a dull period of a few days was noted, but on the whole business has been very satisfactory. In connection with the supply business there has been a very fair demand for miscellaneous material such as pumps, stationary gas engines, farm machinery, contractors' supplies, saw mill equipment, and general manufacturing supplies. Prices of machine shop tools and supplies are gradually being reduced as business increases. An ever increasing variety of tools are being standardized and manufactured in quantities. The field of distribution is also increasing as the service garages are now real prospects for a large number of machine shop supplies and tools. In the portable tool field, which has broadened out largely of late, a large number of real prospects are found in these garages. Reports from various jobbers and machine tool dealers vary. Some claim that January business was better than February business. Others state that February was better and that there is every prospect that March will exceed February.

Non-Ferrous Metals:—The weakness in the non-ferrous metals that has been present for some weeks past is still evident. Copper is down still lower. Tin also has dropped a cent a pound. Very little demand is evident and trading is consequently very light. There have been no outstanding features in the market during the week. Quotations on other metals remain the same, Montreal figures are as follows per 100 lbs.:

Lake copper	17 00
Electric copper	16 75
Castings, copper	16 50
Tin	34 00
Spelter	7 25
Lead	6 75
Antimony	8 00
Aluminum	27 00

Scrap Metals:—This department of the metal business has been very dull for some time past and prospects are not any too good for immediate improvement. Some difference of opinion exists as the quantity of scrap available in the country at the present time. Some dealers claim that the low prices prevailing have not warranted the collection of scrap and that for this reason large quantities have not been reclaimed or collected, which would otherwise have been. This is the reason advanced for the shortage claimed. One dealer states that he recently had great difficulty in collecting a car of stove plate scrap iron to fill an order. This condition may exist, but conflicting opinions are evident. The following are the local quotations:—

PER 100 IBS.	
Copper, light	8 00
Copper, crucible	10 50

Pittsburg

March 1.

PITTSBURG, (Special to Canadian Machinery.)—In most branches of the finished steel trade a further increase in demand is observed this week. As practically all buying is for very prompt shipment, buyers having no occasion to anticipate their wants, the actual production of steel is the best measure of demand, and production has become still heavier, being estimated at 29,000,000 gross tons a year in steel ingots. The rate at the end of December was under 18,000,000 tons, so that the rate has gained by an average of more than a million tons a week since the end of the old year. The rate at the height of last autumn's demand was 23,000,000 tons, in October and November, so that already there is a gain of 25 per cent. yet it cannot be thought that the full force of the spring demand is as yet being felt in actual production.

Steel Production.—Instead of there being compaint about the volume of business, the steel makers regard the improvement as being easily the greatest that could possibly be expected, and in some quarters there is a little note of warning suggesting the possibility that things may be moving a trifle too fast. Some steel producers remark that they "only hope it will keep up" There is room for suspicion that perhaps the condition at the moment is the reverse of the position that plainly existed last summer, when production of steel was far below a rate that would be in keeping with the volume of general business then being done. At that time stocks in the hands of jobbers and manufacturing consumers were being drawn upon. Steel production is now nearly three times the rate of last July, while of course general business is not three times as active. It has merely improved by a moderate amount. Thus it seems barely possible the buyers are now stocking up to a limited extent. In the trade one does not find any statements that this is being done, the common report being that all buying is from hand to mouth and that buyers will not replenish their stocks at all.

Bars, Plates and Shapes.—All finished steel products are not necessarily at bottom as to price, but whatever may be the case with some products, it is quite certain that bars, shapes and plates are very cheap, being quotable now at 1.40c, with a very occasional concession and with some small orders going at 1.45c or 1.50c. It is much more likely that two months hence bars, shapes and plates will be at 1.50c than at 1 30c, and thus there would be good reason for replenishing stocks in a conservative way. The market is at a lower level than buyers themselves expected it to reach, provided there were no reductions in freight rates and no further reductions in wages. While there continues to be much talk about freight rates there is really no definite prospect of their coming down in the discernible future, at least by enough to make much difference in the cost of producing steel, while as to wages there is no talk of reductions.

Sheets Steady.—Sheets continue firm at quotations prevailing for three months past, 2.25c for blue annealed, 3.00c for black and 4.00c for galvanized. The 2.25c base price applies chiefly on the lighter gauges of blue annealed, 12 gauge and heavier often going at plate prices. Incidental evidence that the sheet market really is steady at the quoted prices is furnished by the fact that the American Sheet and Tin Plate Company has opened its order books for second quarter, at the former prices. A little business had already been filled, awaiting the formal opening of books. At the same time the company opened its books for tin plate orders from jobbers for second quarter. To manufacturing consumers books had previously been opened for the half year. The regular price remains $4.75 but on large orders somewhat lower prices are commonly made by independents.

Tubes and Pipe.—No changes in list prices on tubular goods have been made since the reduction of December 15, but shading by independents in standard steel pipe has increased. More often than not in past years the independents have been giving an extra 2½ per cent. in addition to the usual trimmings of the leading interest, and of late there has usually been 2½ and 2½, while in the past week or ten days 2½ and 5 has been given not infrequently. Even this, however, is not sufficient to cause the leading interest to revise its discount card. It is running approximately as well as the independents, about 60 per cent.

Hoop and Band Steel.—Hoops are quotable $2 a ton lower, at 1.80c on orders that are at all attractive. Technically this base price applies to bands also, which were put on the hoop card during the war control, but practically a specification involving bands alone, particularly the wider and heavier, would draw a lower base price. As extras were lowered $4 a ton when bands were transferred from the bar to the hoop card, a continuance of the pre-war practice, with the base price of 1.40c on bars, would mean that bands would be selling at the same net prices as would obtain with the existing card, if the base price were 1.60c instead of 1.80c, and naturally the 1.80c price is shaded somewhat when it comes to bands.

With steel ingots being produced at about 29,000,000 gross tons a year there is represented a production at about 55 per cent. of the entire capacity, the highest rate since January of last year. Considering the different finishing departments separately, their average operation is not as high as 55 per cent., the reason for this apparent discrepancy being that there is always an excess of steel finishing over steel producing capacity. Tin plate mills are operating at about 75 per cent., and sheet mills and pipe mills at about 60 per cent. Bar, shape, plate and rail mills are at less than 50 per cent. but they are all doing better than in December or January.

Pig Iron.—The demand continues very light, while prices appear soft or firm according to viewpoints. Thus the merchant furnaces seem to be standing together more firmly than ever on a quotation of $18, valley, for basic iron, but it is known positively that the last important transaction was at $17.75 or less. A difficulty is that the merchant furnaces are not in control, as there is resale iron in the market as well as iron made by steel works. In Bessemer iron, for instance, the regular furnaces

(Continued on page 68)

Make Sure Where Your Charity Goes

In View of Numerous Calls Being Made on Canadian Manufacturers and Workers for Famine Contributions at This Time, So Many of Which Are Fraudulent, the Following Articles from The Financial Post Will be Found Interesting and Informing

"WHEN THE DEVIL WAS ILL THE DEVIL A MONK WOULD BE"

We have been under the impression that Lenine and Trotsky were a couple of extremely clever, unscrupulous hypocrites for whom the world was hand-picked by the Germans and certain allies, which they officially admit, and sent to head a movement for which plans had been carefully made, to take Russia out of the war and to place that country's wealth and resources in the hands of the promotion syndicate. By slogans and popular theories of handing the properties of the classes to the masses they made a great hit. They themselves, of course, never believed in any such ideals. They got their rivals and opponents out of the way by a gigantic system of organized murder. They prolonged the war and in that way were responsible for the killing and maiming of thousands of Canadian boys. Since the war they have carried on a persistent campaign for creating discontent in Canada—particularly among the wage earners to prevent their working.

Having looted Russia to the limit they are throwing down their dupes, the Bolshevists, blaming them for the wrecking. They are just like groups of financial highwaymen with which trusting investors here are too familiar. They are asking the world to come in and assist them to re-organize the company, buy more bonds. The first offerings did not meet with success. The public was suspicious of the looters. They called back the proposals and proceeded to sugar-coat them; to put the public in a friendly frame of mind for their reception. Their new propaganda was designed to show that the looters were really very great, kindly, in fact, saintly, men; public benefactors who had suffered from the actions of unscrupulous employees. It is true, Lenine and Trotsky admit, thousands of good Russian men were murdered and many more thousands of gentlewomen and girls raped but that was an error of judgement. They are repentant. They are sorry. They are changing the system. The murder-rape policy is being gradually abandoned. The sugar-coating is the linking up of "Save the Children Famine Fund," with the whitewashing of Lenine-Trotsky. A big-hearted genial Canadian, Colonel Mackie, rancher, contractor, promotor, recently made a flying visit to Russia and has come back full of the saintliness of the reformed Lenine-Trotsky crew of murderous highwaymen and the good things they have done and are going to do for Russia—and the old story of prospects of big buying orders for Canada and Russian concessions for Canadians. Under the auspices of the "Save the Children Fund," the gallant Colonel has set himself the task of correcting Canadian beliefs in the unsavory characters of these men. By keeping their thoughts on the children he has succeeded in getting official recognition of the Prime Minister and of Mr. Meighen, leader of the Opposition, with the result of renewed activities of the Bolshevist agents and newspapers and sympathizers in all parts of Canada.

We would be sorry to misjudge Colonel Mackie, but the fact is that so far all his utterances in interviews are about one-tenth famine relief and nine-tenths rehabilitation of Lenine-Trotsky. It is rather a coincidence that over two months ago a propaganda sheet issued by the Berlin Bolshevik agency told of this plan—boasted of its success in developing the appeal for famine relief into a big campaign for the financing of Soviet Russia by western capital. Now they will boast the Canadian Parliament is giving them moral recognition. Is this fair to Canadians?

FAMINE COLLECTIONS

Canada is being intensively organized and solicited for aid to the starving Russians. The strongest pressure for contributions will be on financial institutions primarily, and then on manufacturers, merchants and business concerns generally. They have, therefore, a very vital interest in the question. We have pretty well all we can do taking care of our own destitute at this time. But we can do that and still have some to spare for less fortunate foreigners and particularly for suffering but deserving Russians.

The fact that these people have been so fearfully exploited by, and are still under control of a group of grafting foreigners, is no reason why we should withhold our aid. We should have no sympathy with those who suggest they should be allowed to suffer. The difficulty is to know how we can get our contributions to the real sufferers. We do know that during the last year or more large sums have been collected in Canada which never went beyond the Soviet propagandists within our own borders. Of the many so-called Russian Relief funds, we know of but two that are perfectly legitimate. So crooked are Soviet conditions that persons in this country desirous of sending money to their families in Russia are advised not to do so as only a small per cent., if any, will get to them even through British and United States official channels. The real Russian Red Cross of the war days, still in existence, advise their British colleagues against supporting any of the Soviet schemes and go so far as to say that internal conditions in Russia are morally as bad as in the worst days.

It is the knowledge of these conditions that has made the always generous Canadians hesitate. It has made the British hold back, and the Americans and the French.

Word now comes that millions are going through the indescribable horrors of famine for whom no relief can ever arrive in time. For this condition the policy of the Lenine-Trotsky group in making famine relief the basis for spreading propaganda for recognition and financial aid from foreign countries is responsible. These men have been refusing all relief for the sufferers excepting through their own channels. Persons who knew them have absolutely refused these terms.

The best authority, because of his proved capacity as an organizer and executive and his unusual experience in this particular work, is Mr. Hoover, U.S. Minister of Trade. He knew the urgent need for help. On his advice the U. S. Government gave an initial grant of $20,000,000 to aid in feeding and clothing the starving millions. Lenine-Trotsky prevented his activities for a long time on the demand that distribution must be done through them. But Hoover thoroughly understood their aims and refused. International opinions forced them to give in, but the Soviet agents in Canada and the States are carrying on a campaign against Hoover and his plans. Even the Canadian Government has been privately warned from the Soviet headquarters in New York to avoid his policy or any co-operation with him.

Canadians want to help, but with these facts before them they are at sea and financiers and business men would be well advised to hold up all contributions until the situation is cleared. As pointed out last week, the Government has been committed, probably under the impulse of the moment without proper enquiry, on the advice of one man, to the endorsement of one particular fund "Save the Children." It may be the best, but it is certainly not being conducted on this side on lines that will create confidence. Its promotors here are giving more attention to the rehabilitation of the Soviet leaders than to the famine. In fact, when it was first put out in Canada last year under other auspices it became necessary to bring pressure to bear to stop it. This "Save the Children Fund" was organized by Lord Weardale, whose wife is Russian, widow of Count Tolstoy, and managed by Nansen, a Norwegian scientist-diplomat.

The Friends' Emergency Committee is another that is raising money here. It is apparently thoroughly reliable with a splendid war record.

Finally, there is our own Canadian Red Cross with its wonderful record in South Africa, in this war and since. It is thoroughly organized with foreign connections. When the famine was looming, it took the matter up with the British Red Cross and on their advice has been co-operating through them with the Russian Famine Relief Fund, the chief organization of its kind in England and under the presidency of the Lord Mayor of London. It seems to us Canadians cannot do better than concentrate on, and work through this thoroughly trustworthy channel of good service, and if contributions are large enough, have them administered in our own name.

Since the above was in type several newspaper clippings have come in which show renewed activities by the Soviet Red Cross in several Canadian centres. Such collections are illegal and no money should be given to such agencies.

LONGER GERMAN WORKING HOURS

When Socialist and other radical leaders in Germany like Helmud von Gerlach and Hugo Lindemann come out for a longer working day than the eight hours established after the revolution their program challenges the attention of all industrial countries.

The reawakening of Germany to the law of economics and of sense that mere wage scales cannot give workers what they want without the production by the workers to back up the wage scales means that other nations will have to face the same fundamental truth whether they like it or not. German productivity or German unproductivity, British, American or any other workers cannot let their own production decline without having their standard of living decline, for the simple reason that they can divide only what there is to divide. The more there is produced the more there is to divide; the less there is produced the less there is to divide.

Germany's output of food, clothes and other necessaries of life is not enough under the eight hour system, the foregoing labor leaders now frankly admit, to enable the people to live as they lived before when more work was done and more of everything was produced. That being true of Germany as to its standard of living, something else must be equally true as to German productivity in relation to general productivity. This is that if the German workers speed up their productivity either other peoples of whom the Germans are trade competitors must speed up their productivity or the Germans will conquer the world industrially where they failed to conquer it by force of arms.

Increased production, with a corresponding lifting of living standards, may not always depend upon the length of the working day. In one country or in one industry where productivity has oozed away through men not staying on the job only more hours of work can solve the problem. In another where men are putting in long enough hours but not hard enough licks more human steam will turn the trick. But whether by longer hours in the one instance or by closer application in the other, the productivity of a nation or of an industry must be prevented from running down or its population must have its bread cut in thinner and fewer slices. There is no possible escape from that.

In this country of all countries where hard work from morning to night built up American industrial power and gave the highest standard of living ever known in the world, labor has been grossly duped by labor union politicians and other demagogues into the idiotic belief that it could get a good living without working for it. It might as well expect stones to turn into fruit for the mere wishing.

Whatever the Germans do or do not do in the way of longer hours to bring them more of the needs and comforts of life, the American people are not going to get back to the living ease which they had won by a century of manful toil until they get back on the job in the old American way, with a square day's work for a square day's pay every workday in the year.

VAUCLAIN ON WORLD OUTLOOK

The manufacturing situation in England is bad and will grow worse as sterling exchange, quoted in terms of the dollar, increases in value, according to Samuel M. Vauclain, president of the Baldwin Locomotive Works, who has just returned from a tour, which included almost every country of Europe. In France some discretion is being exercised in not allowing the dollar value of the French franc to advance too rapidly.

The principal reason for this anomalous situation, Mr. Vauclain explained, is the extreme keenness of German competition. The value of the German mark has declined to such an extent that Germany can offer her goods in the open markets at figures that appear ridiculous. He said a mechanic can be engaged in Germany for 100 marks a day or less than fifty cents. Other countries, where it is hard to obtain mechanics at even fifty cents an hour, are finding it difficult to compete with manufactured goods produced under these conditions.

From Havre to Paris, Mr. Vauclain said, he found better conditions than two years before. In Brussels he was surprised by the reconstruction and the improvement of properties. Business in Brussels is slack, but not so bad as here, he said. A temporary hold-up of business has been occasioned by the intensity of German competition. In Germany he visited the Krupp plant, where he found great activity. The new locomotive shops there, he said, are working well, with twelve to fourteen months' work ahead.

In Stockholm all workshops are busy on Russian work. Russia has ordered 1,000 locomotives in Sweden and every effort is being made to speed up deliveries to one locomotive a day. In Norway, he said, he received terrible reports of the awful conditions existing in the famine-ridden portions of Russia.

Mr. Vauclain said a remarkable advance has been shown in Poland in two years. That country, he declared, had a hard time between Germany and Russia, but this position now is destined to make Poland one of the wealthiest and most substantial States of Europe. The development of Russia, he said, must be conducted through Poland.

Czecho-Slovakia is in fairly good condition, although not so good as Mr. Vauclain expected. Austria's situation he characterized as bad, due largely to the splitting-up process through which other States got the vast hinterland upon which Vienna depended so much for its commercial supremacy. Hungary, he said, is better off, but feels the situation keenly.

France, Mr. Vauclain declared, has nothing to worry about. That country is able to compete with Germany to some degree. In England, the shops are running at only about 20 per cent. of capacity, with few orders. The future of the United States for the next five years, the locomotive builders said, depends entirely upon the ability of manufacturers here to extend credits, which, if liberally given, will result in America getting her full share of the world's trade.

Mr. Vauclain said that he did not go abroad for orders and that he "was able to restrain himself." There is plenty of business available if sufficient credit is extended, he asserted, but the Baldwin Locomotive Works does not desire to extend credits to a point at which its capital may be affected. Already credits have been extended to Poland and Rumania, $7,000,000 in the first instance, and further credits to both are probable. Interest has been paid promptly on the $7,000,000 Polish credit and no payment on the principal is due until next year.

As for the United States, Mr. Vauclain said: "Business is not good here." The remedy, he said, is economy, work and thrift. "You can't maintain a payroll," he declared, "if you have nothing to maintain it with.

"I think we will have good business before long, not so profitable as two years ago, but sufficiently profitable to meet all requirements. Prices, wages and the cost of living must go much lower. If we are to continue to compete against the producers of Europe our dollar must buy more than it has been buying."

News From the Industrial Field

W. C. Smith of Toronto, has been appointed to the position of engineer for the town of Oshawa, Ont.

Standard Steel Construction Co., Welland, is in the market for a second hand locomotive crane of from 7½ to 10 tons capacity.

During the year 1921 Peterboro was successful in securing five new industries. This makes a total of 15 in the past three years.

Scottish Fertilizer, Ltd., has begun to operate its new plant at Welland. About twenty-five men are being employed at the outset.

Camile Laurendair, B. A. Sc., of Montreal, has joined the sales staff of the MacKinnon Steel Co., 404 New Birks Bldg., Montreal.

Hardware merchants who import all the oxygen used in the building trades in Jamaica, solicit prices from Canadian firms, for immediate purchase.

The erection of an office building at the cost of $500,000 on Mountain Street, Montreal, is contemplated by Knights of Columbus and the city council.

Action is expected shortly in connection with the proposed bridge or subway for the elimination of one of the level crossings of the G. T. R. at Stratford.

The Messervy Battery Factory of Brampton, Ont., has been purchased by the Arabol Mfg. Co., of New York. It is stated that the plant will be enlarged.

A Birmingham dealer in motor, aeroplane and coach accessories would be pleased to have particulars of any line in motor parts suitable for importation to England.

Work is expected to start about the end of March on the relaying of rails on approximately 100 miles of the London division of the G. T. R. 100-pound rails will be used

An old established London firm is open to represent as buyers or agents, representative Canadian manufacturers and shippers of lubricating oils, tallows, turpentine, rosin, tar etc.

It is reported that the Page-Hersey tube mill at Welland is now in full operation again with day and night shift, between 250 and 300 men having been added to the staff recently.

An Italian firm would be interested in receiving catalogues and price lists of machine tools in general, in order to form an idea of the kind made in Canada, and to ascertain if business can be put through.

Fire of unknown origin completely destroyed the Thornton Rubber Factory at Oshawa, Ont., on the morning of February 22, causing a loss of something in the neighborhood of $100,000 in building, machinery and stock.

A large Dutch Importer in Gorinchem would like to represent Canadian exporters of agricultural machinery in Holland. Wishes to have catalogues and export price lists.

The third annual commercial fair at Brussels, will be held between the 3rd and 19th of April. The preparations give promise that the fair this year will far exceed any others yet held.

The C. N. R. have acquired a large piece of land on the outskirts of Regina, Sask., and will use this for yard extensions, increased grain handling facilities and the enlargement of shops.

Work will commence early this summer on the construction of the two bridges that will connect St. Anne de Bellevue with Vaudreuil. Plans are now being prepared by V. Denis, engineer, Department of Public Works, Ottawa.

A smelting works located in Bristol is in a position to consider offers of type ashes, tin ashes, solder ashes, pewter ashes, brass ashes, tin ores and tin slags, disused electrical accumulator lead plates and lead peroxide and dross from accumulators.

The National Association of Purchasing Agents of the United States will hold its seventh annual convention and exposition at Exposition Park, Rochester, N. Y:, from May 15 to 20. L. F. Boley, 19 Park Place, New York, is convention secretary.

An old-established firm of metal merchants are anxious to extend their connections with Canada for the trade in all kinds of new or old metals. Would like to hear from both manufacturers and merchants in regard to shipments from or to Canada.

There is no possibility at the present time of a plant being established in Toronto by the Canadian Car and Foundry Co., of Montreal. W. W. Butler, president of the company, stated this emphatically when referring to the report that had been circulated recently that such a move was contemplated.

G. E. Morris, sales manager for the International Business Machines Co., Toronto, told Canadian Machinery a few days ago, that business has improved considerably during the last two months. "In fact we are now doing 50 per cent. more business," continued Mr. Morris, "than we were in the early part of 1921, just before the slump started."

Speaking at a luncheon of the C. M. A. recently, Col. F. M. Gaudet, representative of the Scientific Research Council, stated that: "Canada must arm at once for the wars of commerce. The greatest weapon in this war is knowledge. Knowledge of what you can do and can't do with your raw materials. Knowledge of the best ways of doing everything we do."

A delegation from the Canadian Manufacturers Association, representing all parts of the Dominion, will wait upon the Canadian government in the next day or so to present a memorial upon certain subjects which the Association is interested in.

Speaking with regard to the new technichal schools in the east end of the city of Toronto, Trustee Miller of the Board of Education, stated, "We will have British goods in our schools, if we cannot get Canadian goods." He also stated that a Canadian boiler with a Canadian chain stoker could not be secured in Toronto.

Paul Leclaire has been appointed assistant engineer of the Port of Montreal. For a number of years Mr. Leclaire was engineer in charge of buildings, bridges and water supply to the Harbor Commission. Prior to this he was engaged in engineering work with the C. P. R., and with the Dominion Bridge Co.

In last week's issue appeared an item from the report of C. W. Kirkpatrick, Commissioner of Industries at Hamilton, stating that the Ford Company had established headquarters in that city. This should have read: four other companies have established their headquarters in Hamilton, but had not yet commenced manufacturing.

Prospects for renewed activity in the steel districts of Nova Scotia has been brightened by the announcement that the Nova Scotia Coal Co., are making plans to increase coal banking facilities and resume operations in preparation for opening of navigation. It is anticipated that other metal working activities will commence shortly.

J. W. Horne, one of the pioneers of British Columbia, died last week at his home in Vancouver, at the age of 82. He was born in Toronto in 1840 but settled in Vancouver in 1884. He helped to organize the company that built the first street railway in Vancouver and was president and managing director for a number of years.

The total log production of British Columbia for the first eleven months of 1921, from the official returns of logs scaled, has reached 1,650,759,388 feet. During the past year the months of heavy production were June, July and August. Of the total production 1,283,734,106 feet were scaled on the coast and 667,025,282 feet on inland territory.

M. P. Fennell, Jr., who for the past five years has successfully filled the position of secretary-treasurer of the Montreal Harbor Commission, has been appointed to the newly created office of general manager. Mr. Fennell has made a thorough study of harbor activities as they are carried on in all the leading ports of this continent and Europe, and is well fitted for his new duties.

F. W. Pennock has resigned as vice-president and general manager of Cleaton Co. of Canada, Ltd., and will hereafter be solely connected with the firm of Gelinas & Pennock, Reg'd 207 St. James St., Montreal.

Arthur T. Wilson, for some twenty-six years with the Canadian General Electric Co. and recently sales manager of the Earle Electric Co., has been appointed sales manager of Factory Products Ltd., 220 King St., W., Toronto. Mr. Wilson succeeds Mr. Langmuir who is severing his connection with Factory Products Co., to engage in another line of business.

The Gray-Dort Motors Ltd., Chatham, Ont., are planning to put all their local plants on full production schedule March first, according to an announcement made by vice-president Wm. N. Gray. Mr. Gray is most optimistic over the prospects for the year and believes the tide has turned in industry and that the country will gradually resume normal conditions.

It is reported that the Ford interests are considering the establishment of a plant in the Sudbury district. In view of the fact that the tract of land mentioned in the report forms part of one of the principal iron ore deposits in the province, it is thought the intention is to go into the refining of ore and production of steel commodities used in the manufeature of motor cars.

D. F. Fisher, representative for the Enterprise Foundry Co., and the Charles Fawcett, St. John, N. B., stated that there were eleven stove foundries in New Brunswick and that with these he believed the companies he represented were largely interested in the Western trade. His company also bought pig iron from Hamilton as Sydney found the Maritime market for foundry iron was too small.

During the year 1921, the Trail Smelter handled more than four hundred thousand tons of ore, the greatest aggregate in its history. All of this with the exception of about ten thousand tons, was from the properties of the Consolidated Mining and Smelting Co. Gold accounted in the total for 50,000 ounces; silver for 1,173,000 ounces; copper for 57,000,000 ounces; lead for 53,000,000 pounds, and zinc for 53,000,000 pounds.

A firm of manufacturers' agents in Australia, with excellent banking and other references and a successful experience in handling Canadian goods, is desirous of securing the representation of a Canadian manufacturer of bolts, nuts, etc., of the following kinds and sizes for which a good market exists; coach bolts, cup head, square shank, from ¼ to ⅜-inch diameter and 1 to 4 inches in length; counter-sunk head bolts, same sizes; engine bolts, square and hexagon, same diameter, 1 to 3 inches in length; nuts, square and hexagon, ¼ to ½-inch; iron washers, ⅜ to ⅞-inch; pan head rivets, black mild steel, in sizes from ¼ to ½-inch and up to 1½-inch in length. Quotations should be on f.o.b. steamer basis and in Canadian funds.

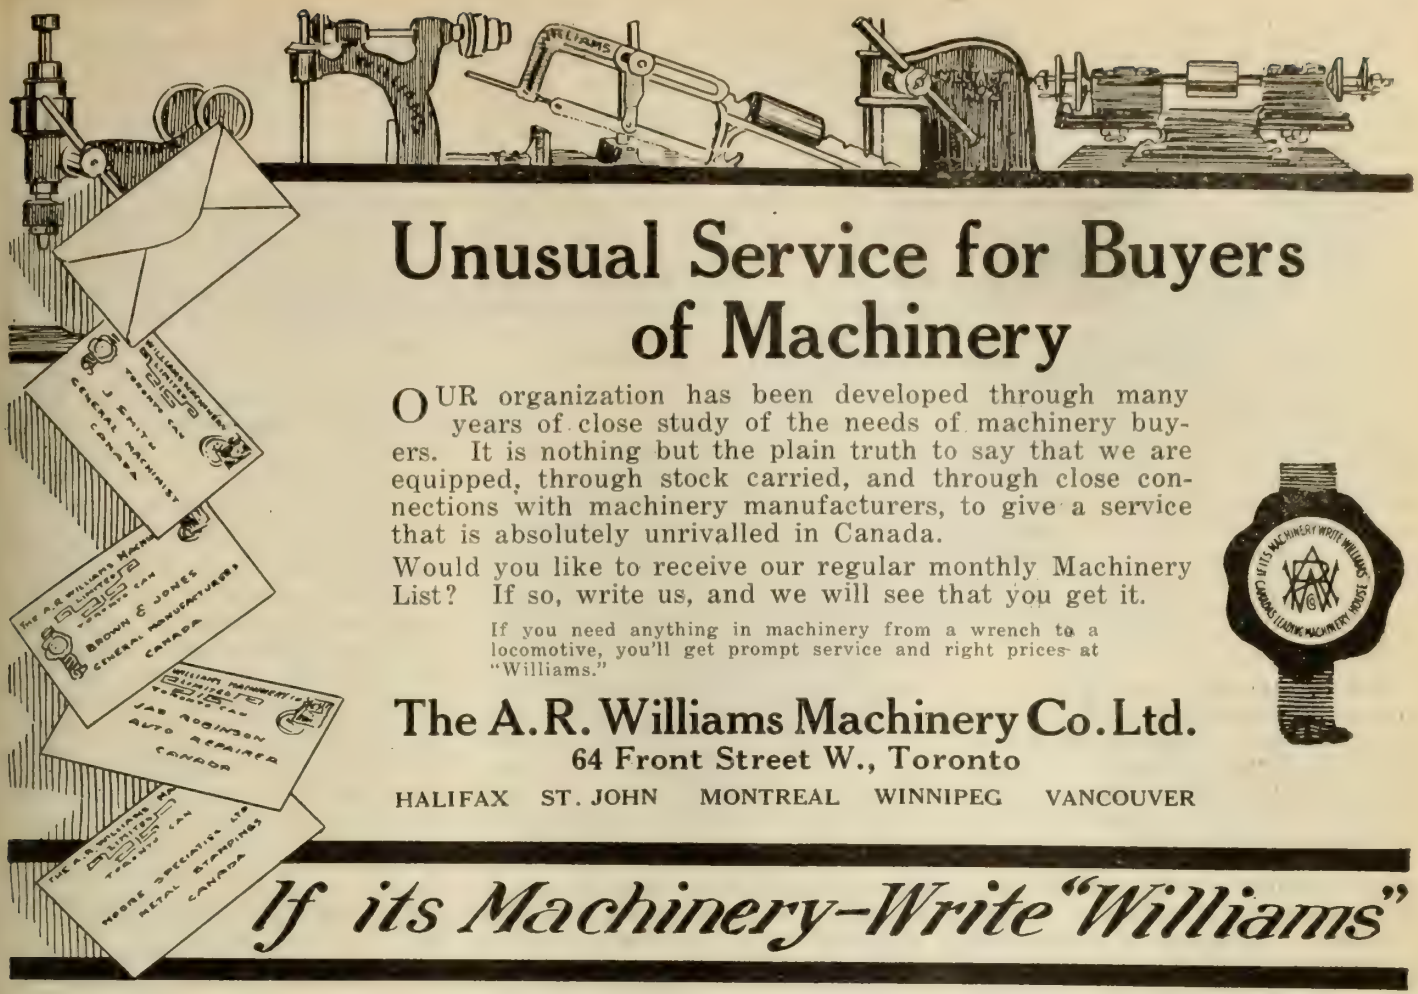
A sharp turn has taken place in export demand for Atlantic Sugar Refineries and big orders for England are enabling the plant to produce to the limit of its capacity or about one million pounds daily. A report covering the past twenty months will be issued shortly, but as this will take in the very severe losses of the latter half of 1920 it naturally will be an unfavorable one.

The Canadian Sales Tract Law according to a statement made at Washington, is to be followed by the House Ways and Means Committee in the Soldiers Bonus Bill that is now being prepared. The special committee of the Ways and Means Committee that will draft the financial positions of the bonus measure has decided to construct the Sales Tract proposal upon the same wording as the Canadian Law.

The Dominion Bureau of Statistics have just published a survey of the manufacturing industries of Quebec province. The total capital invested in the province in 1919 amounted to practically a billion dollars which goes to show how the great natural resources of the province combined with cheap labor have attracted the industry. The value of the raw products used by the manufacturer was $517,587,980 as compared with the finished value of over $988,000,000.

Off shore shipments of lumber during the year 1921 from the mainland of British Columbia amounted to 164,000,000 feet. Shipments to China and Japan accounted for 93,000,000 feet; Australia and New Zealand, 27,000,000; United States, 13,500,000; United Kingdom, 9,000,000; other places 21,500,000. In addition 700,000 bundles of shingles were shipped to the United States Atlantic ports, while 24,600 tons of box shooks went to Australia and Singapore.

It was learned on good authority that a prominent business man of Western Ontario was in Oshawa recently looking for a suitable site on which to erect a large hotel. This man, it is understood, is already in the hotel business, and is desirous of locating here. It is understood that a local real estate firm is making arrangements to secure prices on different properties in town. Lack of sufficient hotel accommodation is acknowledged to be one of Oshawa's greatest handicaps, and word to the effect that a new and modern hotel was to be built here would be enthusiastically received by citizens generally.



The Canadian Department of Railways and Canals has an exhibit depicting the Trent Canal at the motor-boat show in Grand Central Palace, New York. The exhibit, which is attracting widespread attention, consists of a number of very excellent views of the canal system, and specimens of big fish to be found in the Kewartha Lakes, through which the canal route passes. A working model of the largest hydraulic lift lock in the world, at Peterboro, is also prominently displayed. There is also a continuous moving picture of scenes along the canal, which is proving one of the most popular features of the show.

After a suspension of some 18 months, work will be resumed on the construction of the large ocean pier projected by the C. P. R., at Vancouver. This pier, to be known as Pier B.C., will be situated between pier A. and pier B and will be the largest structure of its kind at Vancouver, being of similar width but somewhat shorter than the Ballantyne Pier now being constructed. It will take approximately 18 months to complete the work. The pier will be 800 feet long, 320 feet wide and will carry four railway tracks to enable freight to be handled expeditiously between ship and cars.

The feature of the leather market at the present is the increase that has been noted latterly in the demand for export. The demand from abroad has shown a remarkable increase and dealers are looking forward to the time when they will be able to dispose of between thirty and forty per cent. output in other countries. As a rule the Canadian tanneries have a capacity which exceeds a domestic market by fully 50 per cent. so that it is obvious that if the position mentioned is reached, the trade of the Dominion will be on a much more satisfactory basis. Much of the current stillness in the local leather trade has been due to a number of failures which, though anticipated, nevertheless have a bad effect upon the market. This influence has now been largely eliminated and the trade is in a position to take advantage of any improvement that may develop.

Soon every village in York county will be equipped with public waterworks and other conveniences. At a recent meeting, Engineer H. A. James presented plans and estimates for a water system, and as a result it is likely that the Council will decide to bore test wells and see if a sufficient quantity of water can be obtained to make the scheme feasible. It is proposed to obtain the water from wells. The system would at first include only the business centre and the main streets of the village, but the plant would be large enough to provide for extensions. The cost of a partial distribution plant, pumping station, standpipe and wells was estimated at between $25,000 and $30,000.

The Wallace Shipyard, Vancouver, has been awarded the contract for alterations and improvements to the American Steamer, Admiral Farragut. This was in direct competition with Seattle, San Francisco and Tacoma. The successful bid was $63,000 in Canadian coin. The difference between the Wallace bid and those from the south ranged as high as $40,000. The British Columbia Lumber industry expects to get back into something like its normal stride this year. Reduction in freight rates, coupled with general improvement in Eastern demand, is an important factor. The Atlantic coast of the United States is buying much lumber from this province, the Boston market alone sending in orders for 250,000 feet almost every week.

Unusual Service for Buyers of Machinery

OUR organization has been developed through many years of close study of the needs of machinery buyers. It is nothing but the plain truth to say that we are equipped, through stock carried, and through close connections with machinery manufacturers, to give a service that is absolutely unrivalled in Canada.

Would you like to receive our regular monthly Machinery List? If so, write us, and we will see that you get it.

If you need anything in machinery from a wrench to a locomotive, you'll get prompt service and right prices at "Williams."

The A.R. Williams Machinery Co. Ltd.

64 Front Street W., Toronto

HALIFAX ST. JOHN MONTREAL WINNIPEG VANCOUVER

If its Machinery—Write "Williams"

Technical School Men !

With the co-operation of the Departments of Education of the various Provinces, and with the assistance of principals and instructors, we purpose publishing on March 16th a number that will be a perfect mine of information in the development of Technical Schools to date. There will be such an exchange of ideas, such a volume of practical information, that the number will be regarded as a text book and will be preserved indefinitely for reference purposes.

Articles are appearing in CANADIAN MACHINERY every week, that are just what you have been looking for and for a long time. If you want to know what kind of articles these are—write us for a pamphlet explaining fully.

Subscription rates are $4.00 in Canada and $4.50 in the United States.

Sit right down now and fill out this form and send it to us—with your remittance attached. **You won't regret it.**

CANADIAN MACHINERY,

Citizens of Welland, Ont., are greatly pleased with the news that the Standard Steel Construction Company of that city has secured two large orders. This Welland firm has bid successfully on three swing bridges. One is a hand-power swing bridge, 200 ft. long and is for the Trent Canal at Hamlet, Ont. The other two are 100 ft. power-driven swing bridges for locks numbers one and two on the Welland Canal at Port Dalhousie. These orders will keep 60 men working 10 hours a day for six weeks.

The discount of 3¾ per cent. on Canadian funds in New York, reached this week, is the lowest it has been since sagging of sterling exchange ceased in March 1919. Since that time the discount has gone as high as 17½ per cent., which occurred in February, 1920. The present high value of Canadian funds is influenced by the fact that Canadian foreign trade figures for 1921 showed a favorable balance of about $17,000,000 when most authorities had expected a deficit at the end of the year.

Hon. George Robert Smith, for many years associated with mining activities in Canada, died recently at his home in Thedford Mines, Que. Mr. Smith was born at Newark, New Jersey, February 17, 1860, and came to Canada in connection with the mining industry. He was vice-president and general manager of Bell's Asbestos Company at Thedford Mines, and vice-president and general manager of the Asbestos Manufacturing Company of Montreal. He was one of the founders of the Canadian Mining Institute, and at one time its president.

The greatest danger we have ever faced as business men is to-day, the menace being from United States. In the United States the manufacturing plants are at present over-built with a production capacity of 25 to 40 per cent., greater than the necessities of domestic demands. They have much unemployment there also. We must not stop in this idea now. We must go forward in a larger way and get our merchants to clear their stocks of all but Canadian goods, with perhaps a few necessary exceptions in British lines. "We must nail to the mast the Made-in-Canada sign and work to keep it there. Not only should there be another show next year, but it should be double the size of this."

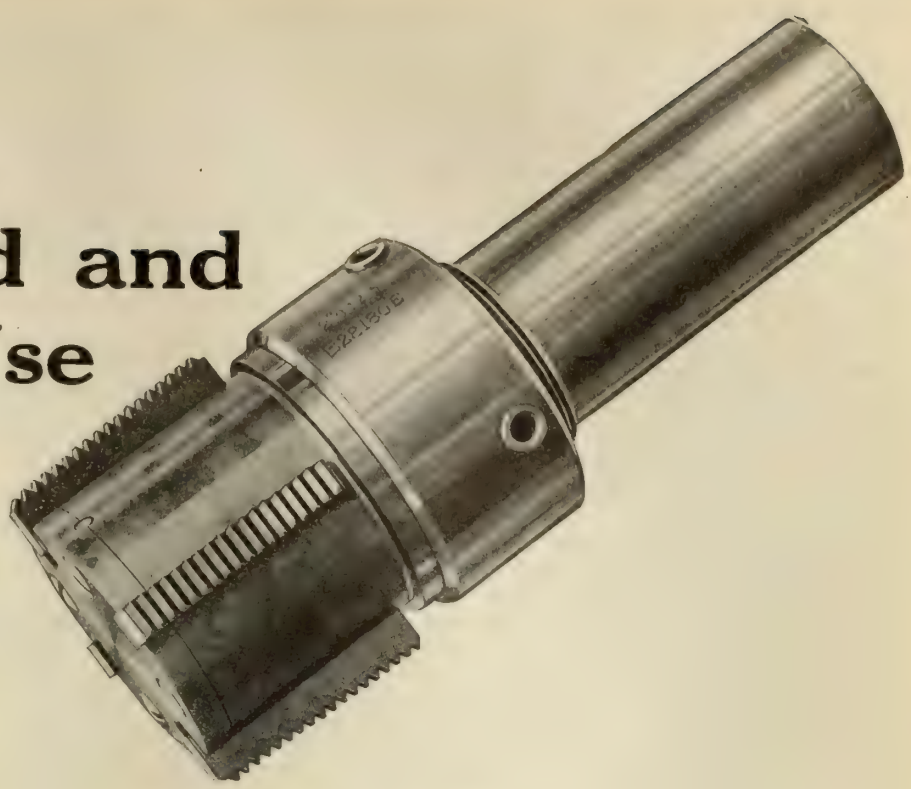
The estate of the Kaministiquia Pulp and Paper Co., consisting of a fully equipped ground-wood mill and 16 acres of property under a 99-year lease from the corporation of the city of Port Arthur, was sold at public auction for $175,000 to Geo. P. Berkey, vice-president and general manager of the Consolidated Water Power and Paper Co., of Wisconsin Rapids, Wis. The mill was constructed and completed in January, 1921, at an estimated cost of $450,000, and was in operation less than three months. U. M. Waite was president and general manager. The Consolidated Co. is capitalized at $1,600,000, with a surplus of $5,991,000. It is stated to be the intention of the company to open the mill at once.

At the present time the Dominion Government is in for a busy time with Hon. John Oliver, Premier of British Columbia, and a big delegation representing British Columbia Boards of Trade. One topic of discussion is the freight rate from that province east; and another concern is the dry dock at Vancouver and the half built one at Victoria. The work on the dock yard has been practically shut down. Government assistance with these is asked. There are reports in Ottawa that these delegations from British Columbia would like to unload the Pacific and Great Eastern Railways upon the national system. Planned originally to link the Grand Trunk Pacific with Vancouver, this railway never reached within 40 miles of that city. It has already cost some 40 million and perhaps some 30 million more would be required to complete it.

The J. D. Brill Co., of New York, which extended operations into Canada during 1921, and secured enough business to purchase the plant of the Preston Car and Coach Co. of Preston, Ont., has issued a report for the year 1921, which shows a large falling in the output of the company's plant The sales values total $7,647,898, compared with $17,537,000 in 1920 and $14,510,000 in 1919. The report goes on to say "While the company has been doing business in Canada for many years, it seemed that it was necessary to extend operations there, and a new concern was formed, Canadian Drill Co. Limited. The new company has leased, with an option to purchase, a moderate sized plant at Preston, Ont., which was put into operation September 1st, 1921, and now has sufficient work to keep it running at full capacity. There has been great improvement since the first of the year in employees received and in a prospect for business, which should be placed during the current year. The large number of electric railways are considering seriously the purchase of cars which they badly need."

Toronto is to have a large car building plant. The Canada Car and Foundry Co., of Montreal, which has already turned out 200 cars for the Toronto Transportation system, is seriously considering starting a plant in Toronto. Sites on the water-front at the foot of Bathurst Street, Toronto, once the Dominion Shipbuilding plant, and others, have been carefully looked over with a view to purchase or lease for the headquarters of the new Toronto industry. The Canada Car and Foundry Co. have been greatly encouraged by the prospects for business in this city and the province. When this system was taken over the Toronto Commission sent out word that any company locating in Toronto would receive special consideration when orders were given for new equipment, and mention was also made about the heavy repairs which the Commission would have to give out in connection with the operation of the system.

The 45,000 K. V. A. generator, now nearing completion at the plant of the Canadian General Electric Co., at Peterboro, will probably be ready for shipment to the Hydro-Electric Power Commission Power house at Queenston early in April. This unit is stated to be the largest of its kind in the world and will require 25 freight cars for its transportation. It will take several months to install. A twin unit is now under construction at the Peterboro plant.



The International Nickel Corp., according to wire information received, disposed of a larger quantity of refined nickel during January 1922 than in any corresponding month in history, and incidentally added to its treasury surplus. The producers are formulating plans for an aggressive campaign to increase the sales of refined nickel and Monel Metal for commercial uses and by economies made, the metal in future will be in keen competition with brass and copper. They also intend to assure its increase for use in the manufacture of steel, which will undoubtedly have to be sold at a lower price than they have been in the habit of receiving, but operation will not likely be impaired as they can cover their maximum production without fear of exhausting their reserve under one hundred years, having millions of tons of ore yet untouched, and millions of tons blocked out and proven by Diamond drilling. The future of the nickel industry in the light of recent scientific readers, now appears brightest.

New Appointment To Harbor Board

The appointment of Dr. W. L. McDougald to the position of chairman of the Harbor Commission of Montreal, has been officially announced. Mr. McDougald is president of the Century Coal Company, a director of the Hollinger Mines, a director of the Dominion Steel Corporation; president of the Sterling Bond Corporation, a director of the Canada Steamship Lines, Ltd.; a director of the British Empire Steel Corporation. He is also president of the Ogdensburg Coal and Towing Company, which organization are the agents for the Dominion of Canada for the Delaware, Lackawanna and Western Coal Company, one of the largest coal companies of the world.

During the war period, Dr. McDougald acted in an unofficial capacity as aid to Mr. C. A. Magrath, when the latter was Controller of Fuel for Canada, and was of much assistance in obtaining an equitable distribution of available supplies. He has travelled extensively, and while doing so has made extensive study of transportation matters and port facilities throughout the world. The new official is the youngest chairman the port of Montreal has yet had. He is but forty years old, and was born in Glengarry, Ont.

A Tap For Both Hand and Machine Use

Geometric Adjustable Non-Collapsible Tap

Right on the Lead

A Threading Tool that is "making good" in the reduction of production costs—the Geometric Adjustable Non-Collapsible Tap.
It is especially valuable on machines having no means of closing a Collapsing Tap or for some other reason not permitting the use of a Collapsing Tap.
The Geometric Tap has the advantage of use either as a hand tap or as a machine tap.
The Tap is not equipped with the collapsing device, but has all the other advantages of a Collapsing Tap. Being adjustable, correct size is always maintained.
Chasers are readily removed for regrinding, and when finally necessary to renew the chasers, this can be done at slight cost. A great saving over renewing the entire tap.
Each size tap accommodates chasers for a range of diameters.

Reducing production costs is no new occupation for Geometric Screw Cutting Tools and Machines.

Let Us Prove It.

THE GEOMETRIC TOOL COMPANY
NEW HAVEN CONNECTICUT

Canadian Agents:

Williams and Wilson, Ltd., Montreal

PITTSBURG MARKETS
(Continued from page 58)

had been holding to $19.50, valley, but the Cambria Steel Company, Johnstown, decided a few weeks ago to make merchant iron and has now sold a lot of several hundred tons to a Pittsburg district consumer at the equivalent of $19, valley. Foundry iron remains quotable at $17.75 to $18, valley.

Probabilities now are that the reduction in Lake Superior iron ore for the 1922 season will be in the neighborhood of a dollar a ton, made up of concessions by producers and by decreases in freight rates, the regular price being at Lake Erie dock, not at mine. Mesabi non-Bessemer last year was $5.55, at Lake Erie dock, there having been a reduction of $1 a ton from the 1920 price, putting the market back to the 1919 level. The actual market price will hardly be developed for two or three months yet. The question is whether the decline in pig iron prices has discounted the prospective decline in ore.

Connellsville coke is holding the advances reported last week but has not stiffened farther. Spot and prompt are quotable at $3.25 to $3.50 for furnace and at $4 to $4.25 for foundry, per ton at ovens.

Don't let your machine cut wind when the boss isn't around.

Don't try to shift the responsibility for any spoiled work, own up like a man.

HAVE MANY ORDERS ON HAND

"WE ARE experiencing very good business. In fact some of our present orders will not be completed for at least three months or more." This was the cheering news which E. M. Jones, sales manager for W. H. Banfield & Sons, gave to Canadian Machinery during an interview a few days ago.

This firm is just completing a large shipment of electrical goods and phonographic parts to New Zealand, and a short time ago sent various of their products to Japan. They are doing quite a bit of export business, having sent material to a number of other foreign countries.

They are developing their range of electrical goods, more extensively and have engaged H. A. Shroder, who has had twelve years experience in that business, to supervise, and develop new lines. In addition to their regular electrical products, they are going to place on the market a levoriler chain socket which breaks at 660 W. They are also going to make keyless sockets, rotary switches, heat switches for stoves, and other lines. Their push switches, and in fact all their lines, are placed under very exacting tests, these being viewed by Canadian Machinery.

They are also selling some of their war time equipment and are re-arranging their other tools in order to have the various departments in the best possible sequence. The work entailed in this move is considerable, but will be worth while when completed. In a later issue we will have more regarding the activities in this plant, touching upon production methods adopted.

In an article dealing wtih the metallurgy of copper, contributed to the Journal of the American Institute of Mining and Metallurgical Engineers, Mr. E. P. Mathewson attracts attention to the importance of the by-products of the smelting operations. Under this head the following may be mentioned:—Sulphuric acid, liquid sulphur dioxide, gold, silver, lead, zinc, zinc oxide, zinc dust, test lead, blue vitriol, litharge, cadmium, bismuth, thallium, selenium, and its compounds, tellurium, arsenic, fungicides, insecticides, phosphate fertiliser, aluminum and its compounds, antimony, lithopone, platinum, palladium, iridium, nickel and its compounds, fire-brick, and common brick.

BUBBLES IN GLASS

Bubbles which are detected in glass in the process of manufacture must of course be eliminated, and the only way would seem to be to stir or otherwise manipulate the materials until they are brought to the surface. A German firm, however, has applied for a British patent for subjecting the glass while in a soft state to a pressure of at least 200 atmospheres so that the imprisoned gases will be absorbed.

BANFIELD

METAL STAMPINGS

Manufacturers of metal specialties are coming more and more to realize the utility and economy of metal stampings over castings and expensively machined parts.

Have you investigated this possibility as applied to **your** manufacturing problems?

Bring your problem to us. With our extensive experience and complete plant for turning out metal specialties of all kinds, we can undoubtedly be of service to you.

A new safety code for the use, care and protection of abrasive wheels has recently been approved by the American Engineering Standards Committee and released for publication, the date of approval being February 11, 1922. This code has been in the process of preparation for about two years, and the announcement of its official approval will be gladly received by a large number of individuals and organizations who have been waiting for an authoritative publication on this subject, as well as by the many societies, associations and individuals who had a hand in its preparation.

The code was prepared under the rules of procedure of the American Engineering Standards Committee and has as its sponsors the International Association of Industrial Accident Boards and Commissions and the Grinding Wheel Manufacturers of the United States and Canada. The new code is a distinct improvement over the codes previously issued by the grinding wheel manufacturers, and contains much information not found in any other publication. The size and scope of representation of the organizations sponsoring and endorsing the code give it an air of authority which cannot but commend it to the careful consideration of everyone interested in any way in grinding wheels. The code is now in the hands of the printer and will be ready for general distribution about the middle of March, 1922.

How to Get Greater Production at Lower Operating Costs

EQUIPPING the tool room with one or more handy DUMORE high-speed GRINDERS means an increase of output and a lessening of costs on intricate grinding work. Because of their adaptability, these efficient grinders eliminate the need for costly tearing down of jobs and consequent wasteful delays.

Durably built in six useful styles and sizes, these compact high-speed grinders have long ago become indispensable in many varied industries. DUMORE grinders combine perfect running balance with correct cutting speed and work with a total lack of end play and absence of vibration—insuring speed and accuracy on the most delicate jobs.

The above picture shows a DUMORE grinder attached to the toolpost of an engine lathe at the Geometric Tool Company, New Haven, Conn. A cam for a die head has just been machined and the hole is being accurately ground without tearing down of the original "set up." Result—faster work at a decreased operating cost.

Let the DUMORE solve **your** grinding problems. Ask your dealer about them or write us for descriptive literature, and learn how DUMORE economy saves time and money. Write **to-day.**

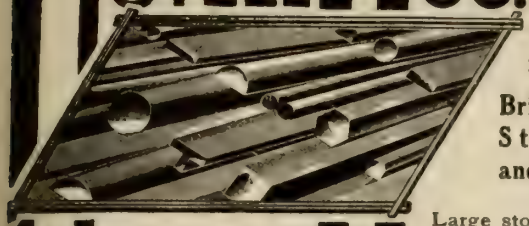
Machine Shops
Metal-working Plants
Power Plants
Foundries
Industrial Shops

You can establish a contact with prospective buyers by cultivating their business in these papers—each exclusive in its field—

CANADIAN MACHINERY AND MANUFACTURING NEWS—published weekly, serves the Machinery, Iron and Steel and General Metal-working industries, reaching proprietors, purchasing agents, business men, works managers, superintendents and foremen. All Canada's important manufacturing and metal-working shops are covered, machine shops, engineering plants, railway shops, iron and steel mills, farm implement manufacturers and, in fact, all kinds of shops where metal-working is carried on.

POWER HOUSE—published semi-monthly. It serves steam, electrical, water and gas power plants and refrigeration plants throughout the Dominion. It reaches plant owners, their purchasing agents and stationary engineers and firemen. It goes into the power houses of all general manufacturing plants, pumping stations, mining industries and railroads.



CANADIAN FOUNDRYMAN AND METAL INDUSTRY NEWS—published monthly. Serves all the grey iron, steel and non-ferrous foundries in Canada. Reaches owners, superintendents and foremen.

Good distribution of your product is desirable—good salesmanship is essential. Our proposition possesses possibilities that will be sure to interest you. Full information on request.

PARKER VISES

Fit Every Form of Work

Parker Vises take in 70 sizes and a style for every trade or shop. For small repair shops and garages—for the engine room—for experimental departments—and for great machine and railroad shops using hundreds of vises, there is a "Parker."

Parker Vises have been in the prominent shops of the U.S.A. and Canada for 80 years. Good design and good stuff placed and kept them there.

Write for domestic Folder No. 12, or Export Offer No. 12C.

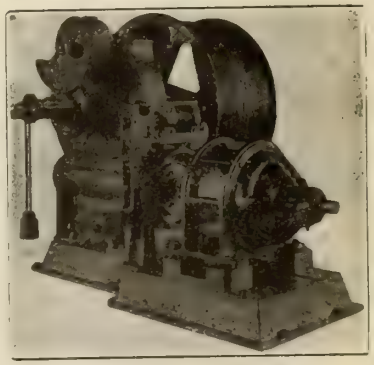
Showing the method of using the SHERMAN "Protection" DRESSER. It is a handy tool provided with a safety hood to protect from flying sparks.



Grinding Wheels
Need Desmond-Stephan Dressers

Desmond-Stephan Dressers keep the surface of the grinding wheel always in good condition for free cutting. They are the legitimate solution to the grinding problem.
For every grade of work there is a specially designed Dresser. For the ordinary shop grinder specify "Diamo--Carbo." The best way is to tell us your work and we will send for a free trial a liberal supply of tools. Write us today.

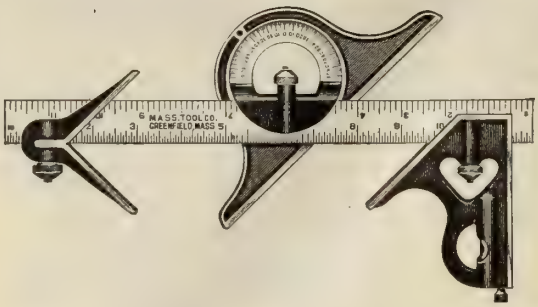
Roelofson Elevators

Reduce Freight Handling Costs



Worm-Geared
Belted or
Direct Drive

They keep costs down low by running smooth, safe and noiseless. Brake is self-adjusting. Gears are strongly made of phosphor bronze. Worms cut from solid steel forging. Construction is self-oiling and dust-proof. Capacity 1,000 lbs. to 10,000 lbs. A complete line of Electric, Hydraulic and Hand-Power Elevators.

Roelofson Elevator Works
GALT, ONTARIO

GOODELL-PRATT

1500 GOOD TOOLS

Try Before You Buy

Why buy precision tools blindly on reputation? Why not test each tool yourself before you buy it?

If it's a Square you want, test it out with another and make sure you get a light-tight fit.

If it's a Steel Rule, "mike" its length and get one that is correct.

If it's a Micrometer Caliper or Depth Gauge, check it every .010 inch with a set of blocks.

If it's a Feeler Gauge, measure the thickness of the leaves.

Goodell-Pratt Precision Tools welcome any test you want to make, because every one is made with good old-fashioned honesty and care. We don't ask you to take our word for it; all we ask is that you give Goodell-Pratt Tools a fair test.

Supplying the Demand for Good Wrenches

There has always been a big demand for **good** wrenches. There always will; good wrenches are hard to make. Machinists who know that good wrenches are the cheapest in the end find in Armstrong products longer service, due to best steel, accurate machining and heat treatment.

In addition expert designing of a wide range of styles insures prompt satisfaction on your order — no matter what it may call for.

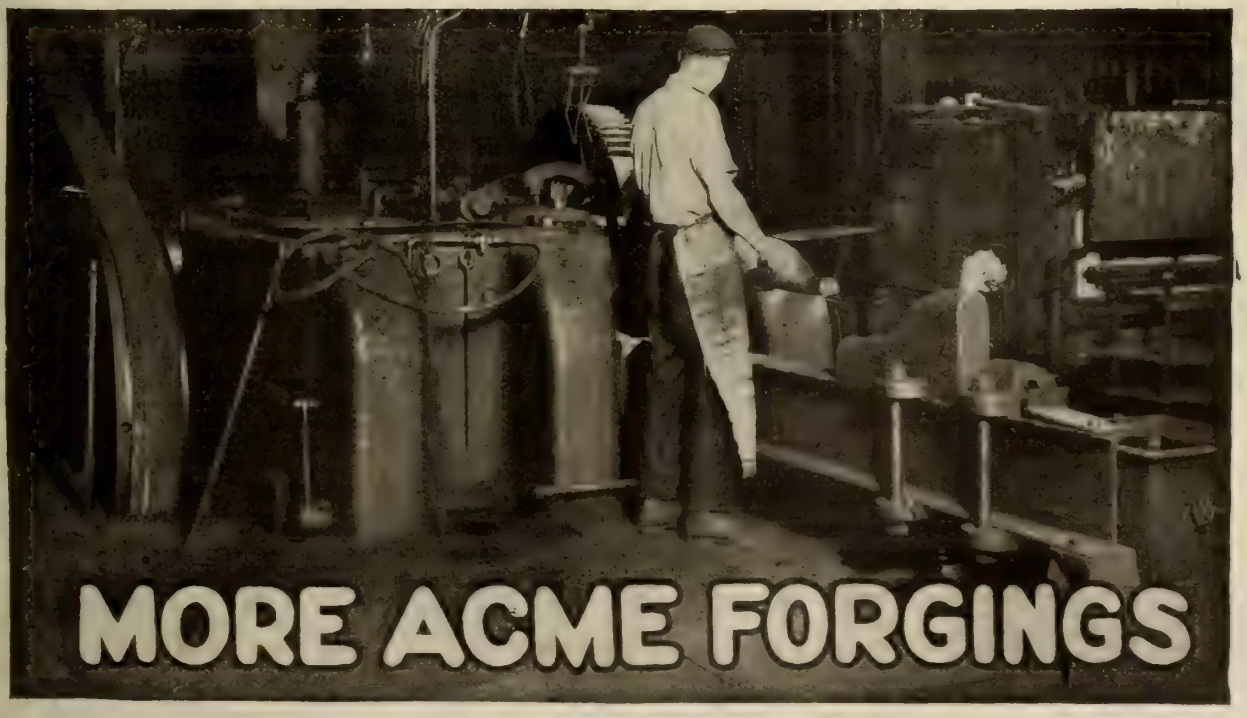
Acme Forging Machines

Production At Lower Cost

AN instance of how Acme Forging Machines are employed to give increased output at a lower cost is seen in the forging of auto pinion shafts.

Upsetting is completed in three operations, the stock used is $1\frac{1}{8}$" steel. The cold end of each shaft is placed against stop, then heated end in the die. A step on treadle completes first operation. This being a two-operation die the work is next placed in its lower section, the treadle again stepped on, and the second operation completed. After a quantity of work has piled up the dies changed and a single operation at opposite end of shaft completes the part.



Acme Forging Machines include within their range all kinds of bolts and forgings possible on ordinary Forging Machines as well as many intricate shapes not possible on ordinary types. The Acme Catalog fully explains its possibilities—write for it.

GALT, ONT.

Do Your Castings Cost Too Much?

A rearrangement of your patterns might cut their cost 25 per cent.; a different method of molding them might double your production at no increase in molding cost. We can advise you and we have expert metal and wood patternmakers who are able to make any changes that may commend themselves to you.

If you need some new Patterns

send us a sample, blueprint or sketch, and ask for our advice. It won't cost you anything. If our advice is good and commends itself to you, it is only fair to assume that our work will be equally satisfactory, and we need the work as badly as you need the patterns.

We are in a position to do turning, boring, drilling or other semi-finishing operations on castings supplied by us. Ask us.

We have for our and your requirements, a large stock of assorted White Iron Stars, suitable for light agricultural to medium weight machinery castings, while they last, at 8 cents per lb. F. O. B. Galt.

Canadian Machinery BUYERS DIRECTORY

If what you want is not here, write us, and we will tell you where to get it. Let us suggest that you consult also the advertisers' index—last page of book, after having secured advertisers' names from this directory. The information you desire may be found in the advertising pages. This department is maintained for the benefit and convenience of our readers. The insertion of our advertisers' names under proper headings is gladly undertaken, but does not become part of an advertising contract.

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

The Directors Make a Discovery !

Production is not up to standard. Business has fallen off. They decide to place orders at once for

New Machinery

Some manufacturers often hesitate when a proposed new machine shows pronounced advantages, complaining of the item of first cost. But the progressive part of the world is beginning to realize that we are coming to a time when expenses and complicated machines—machines that can almost think—are the things they must have if they are to keep up with the procession.

It is a matter of history that where labor-saving machinery is not encouraged, trade ceases to flourish. Work-shops and mills behind the times in their equipment are on the road to padlocked gates and disaster.

Have the courage to establish a scrap heap. Keeping up the plant and discarding out-of-date machinery is a clue to a great part of Canadian manufacturers' supremacy.

H. W. PETRIE LIMITED, TORONTO and HAMILTON

MACHINERY AND SUPPLIES

Make sure that your Starrett Tool kit is as complete as that of any man in the shop. You can't afford to be handicapped by poor tools.

EVERY one of the new Starrett Tools fills a definite need of Canadian Machinists. Take these No. 423 Starrett Rules and Holder, for instance. Every machinist knows what a nuisance it is trying to get a measurement in one of those small hard-to-get-at places where his regular rule won't go. With a tool like this it's easy! It's the same way with the other new Starrett Tools—every one of them meets a definite need. They're all described and illustrated in a special Supplement to the Starrett Catalog No. 22"3" A copy of either Supplement or Catalog—or both—will be sent free to any tool user (or dealer) on request.

FIFTY YEARS OF QUALITY

Mr. E. Ficiency Says:

There was a big waste in our materials—stationery was being spoiled, books were becoming office-worn; it was hard to find supplies we had, and we bought more because we thought we were out.

Then we added to our office equipment a

DENNISTEEL
Made in Canada

Stationery Cabinet

Now we know where everything is—our supplies are protected from dust, from mice,—and what is most important of all, **from fire.** The cabinet is really a handsome piece of office furniture, and such a saver of space!

DENNIS ALSO MAKE

Steel Lockers, Steel Shelving, Steel Bins, Steel Lavatory Compartments, Steel Chairs and Stools, etc. Ornamental Iron and Bronze, Commercial Wirework, of all kinds, General Builders' Ironwork, "Boca" Solid Steel Sash.

PRESSES—DIES and SPECIAL MACHINERY

BLISS

Battery of Stiles Adjustable Bed Presses in production

STILES PRESSES WITH ADJUSTABLE BEDS

This type of press with adjustable and removable table is built in several sizes, either as flywheel or geared presses. Weighs 2,300 to 10,500 lbs. The adjustable table permits the use of dies varying considerably in height, making them specially convenient for bending and forming operations and for work requiring a longer stroke than is practicable on the Stiles standard pattern of presses.

For special work as shown in the illustration they are fitted with special tables.

There is a Bliss press of some type that will fit your particular need. Write us your requirements.

Dominion Oxygen is Organized for Service

TO keep pace with the rapidly increasing number of users of Dominion Oxygen and to fill their orders the same day as received, six perfectly equipped Plants and Distributing Stations have been located at strategic manufacturing and shipping centres.

The policy of Dominion Oxygen Company, Limited, to supply only pure oxygen in light weight, conveniently handled cylinders of the newest and most improved type and to make prompt shipments by the shortest route, will be maintained by the addition of more plants and distributing stations.

The six units now in operation will be increased from time to time, not only to keep pace with, but to anticipate the demand for oxygen service.

Be Sure To Get Our Price First. Get in touch with our nearest Plant or Distributing Station today and let us quote you—you owe it to yourself to get this better service.

The chain of Dominion Oxygen Plants and Distributing Stations now includes the important cities of Montreal, Toronto, Hamilton, Welland, Merritton and Windsor. Send your order to the nearest Distributing Station today for a sample cylinder, which will be shipped immediately.

A trial of Dominion Oxygen will make you a regular user, because you will both save money and get better service.

You can establish a contact with prospective buyers by cultivating their business in these papers—each exclusive in its field—

CANADIAN MACHINERY AND MANUFACTURING NEWS—published weekly, serves the Machinery, Iron and Steel and General Metal-working industries, reaching proprietors, purchasing agents, business men, works managers, superintendents and foremen. All Canada's important manufacturing and metal-working shops are covered, machine shops, engineering plants, railway shops, iron and steel mills, farm implement manufacturers and, in fact, all kinds of shops where metal-working is carried on.

POWER HOUSE—published semi-monthly. It serves steam, electrical, water and gas power plants and refrigeration plants throughout the Dominion. It reaches plant owners, their purchasing agents and stationary engineers and firemen. It goes into the power houses of all general manufacturing plants, pumping stations, mining industries and railroads.

CANADIAN FOUNDRYMAN AND METAL INDUSTRY NEWS—published monthly. Serves all the grey iron, steel and non-ferrous foundries in Canada. Reaches owners, superintendents and foremen.

Good distribution of your product is desirable—good salesmanship is essential. Our proposition possesses possibilities that will be sure to interest you. Full information on request.

Reduce Your Costs by Better Trucking Methods

Profitable Expenditure—Keep Machines Supplied With Work—Tracing Cause of Delays—Design Body to Suit Requirements—Mechanically Operated Trucks Facilitate Handling of Material

By J. H. MOORE

CAN you save money, by spending money? This sounds like a foolish question at first, but it is one that every executive should be interested in, especially at the present time when elimination of needless expense is so necessary. There are many ways in which an executive can spend money wisely on new equipment, saving expense in the long run, through the improvement in production, quality of work, and so on. Such saving is not confined to equipment, but to cover all sources of expense leak in one article is impossible, so that in the present material we will touch upon only one method of reducing factory expense.

A well managed plant always has a steady stream of material arriving at the various machines and benches. Whenever a tie-up occurs, it means a loss of actual cost to the plant owner, for wages, overhead, etc., must go on just the same. Tracing the cause of delays, through material not arriving at machines in time, it is generally found that inter-shop transportation methods are at fault. In other words, either the wrong type of truck is used for the purpose, or worse still, insufficient trucking equipment is installed. Either condition makes for lower profits.

The cost of handling a product has always been a vexatious one to executives. They often find, upon investigation, that more time is taken up in handling, than in the actual machinery operation. This of course should not be, and the remedy should be applied at once.

If you have not considered the matter of handling costs in this light before, it is not too late to do so. Proper handling of work is an ever increasing problem, so that one can truthfully say that the value of inter-shop trucks to a business largely depends upon the extent to which executives make use of this aid. Properly used, trucks can reduce production costs, and increase the efficiency of the workers. So many different types of trucks are obtainable, that executives have a very wide choice. Not only that, but they can secure definite data from the firms making such trucks regarding the savings effected. These figures generally come from the managers and superintendents of plants who have used trucks with success so that they can be thoroughly relied upon.

The Question of Cost

First cost is a minor consideration when viewed in comparison with future savings. That is to say, do not always purchase the cheapest equipment you can find, unless you feel sure it is the best for your purpose. For example:—

Suppose you were contemplating purchasing some equipment which would cost you from 35 to 40 per cent of your estimated savings. On the face of it, this looks like a mighty good proposition, but suppose we consider a second case. Another type of equipment can be purchased at 60 to 70 per cent. of estimated savings, later reducing handling costs 100 per cent. Which is the better proposition? Naturally the last mentioned, so that it pays to study more than the first expense only.

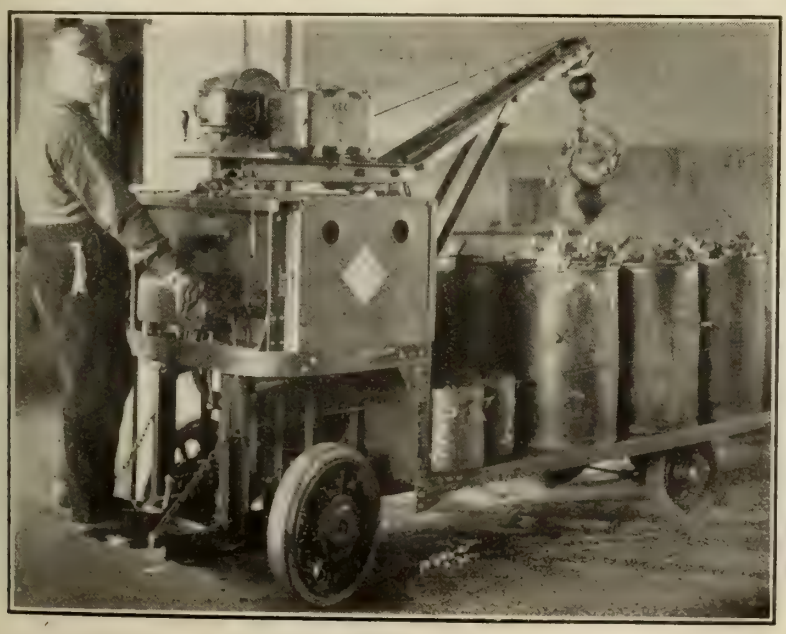

Fig. 1.—Type of truck used in Ford plant.

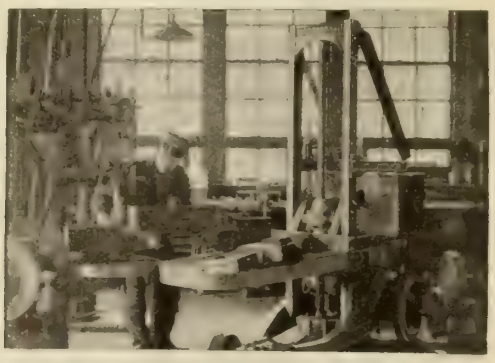

Fig. 2.—Showing use of lifting truck in machine shop.

We know of a case where the saving in handling per year amounted to $750,000, through the use of proper trucks. Suppose first expense had been considered as the chief point in this case, the equipment purchased might not have given such favorable results. True, this was a large concern which effected such an enormous saving, but smaller shops can benefit in like proportion.

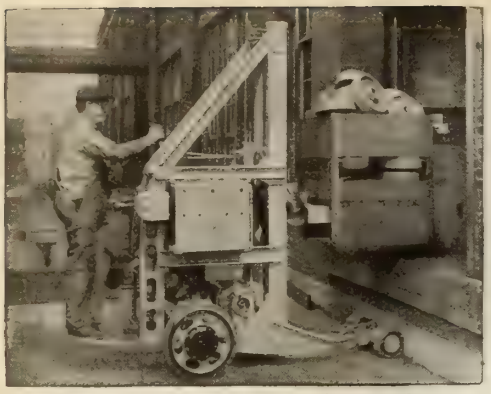

Fig. 3.—Showing use at various levels.

First, we have the hand-operated truck. These vary in character, but the principle is the same, viz., the human element does the necessary pushing or pulling. Usually the higher grade trucks are equipped with ball bearings, this reducing to a large extent the energy required for their operation. A ball-bearing truck, even though loaded to capacity, is not a difficult thing to move. Thus, the workman's strength is not overtaxed.

The type of platform, top, or rack, should be studied carefully. Figure on the work which has to be trucked, how it can best be loaded and unloaded, and, in many cases, it may be found wise to make a special shaped body to suit the nature of the work. A little extra expense on the body will more than pay for itself in the end.

Then we have the electric type of truck, such as shown in the various illustrations in this article. These trucks get their motive power from batteries, these being charged at regular intervals. A large number of firms throughout Canada have found this style of truck to speed up production and handling time in a wonderful manner. There is no need to comment on the method of operation, and the simplicity of steering is one of the chief assets of this type of inter-shop truck.

Savings Secured

The truck can be arranged to draw small trailer cars, taking raw materials from one section of the plant to another and so on, we have figures on file which show that in a certain automobile factory the trucking gang was reduced by 64 men by the first installation of eight trucks of different types, these varying with the class of work being handled. The average load was not over 1,000 pounds, and since the installation of the system we speak of, there has been less damage and breakage of parts, and practically no congestion as formerly. Of course a large cash saving also resulted. Rather than quote further actual examples of saving, we will discuss how electrically driven trucks, fitted to suitable bodies, can be used to advantage in the shop.

Take for example Fig. 1. The type of truck shown is equipped with suitable crane, and is used in the Ford Motor plant with good success. Others of like nature speed up and down the factory, taking parts from one machine or department to another. Note the varied collection of castings handled; one can readily understand how much quicker this method is than the hand-trucking way.

Fig. 2 shows another type of electric truck, which has a lifting device, this allowing the operator to bring the platform up to any desired height within the capacity of the framework. As will be seen from the cut, the drill operator has no trouble getting his casting on to the table. Not only does this save time, but it increases efficiency, as the workman is not straining himself lifting all day long.

Fig. 3 shows another use for this style of truck. Here we find that the operator has lifted up his platform to suit the door sill level. Many factories have yards such as shown, and if ordinary trucks are used it means waste of time and double handling. With the

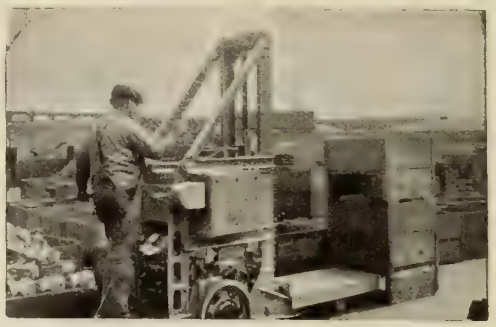

Fig. 4.—Note type of construction at bottom of holding racks.

method shown, the material is soon landed into the other department.

Fig. 4 shows another use for the lifting platform type of truck. In Figs. 3 and 4, it will be noted that the bottom part of material-rack is shaped to suit the entry of platform. This is most important, and speeds up handling considerably. It proves the former point mentioned, viz., that it pays, not only to study the truck, but the style of storing and piling used in conjunction with the truck.

Then there is the electric locomotive shown at Fig. 5. This style of hauling aid has proved of great value in taking heavy or light castings to and fro, especially in the larger-sized plants. It can handle very heavy loads, allowing many cars to be hauled at one time.

We have only scratched the surface of trucking possibilities in this short article, but sufficient has been shown to prove that trucks are very necessary and valuable to a well conducted business and the extent of their value depends almost entirely on their wise application to the work on hand.

AUTOMATIC FURNACE CONTROL

The furnace may be said to be almost the first industrial appliance ever produced, since it is in furnaces of some sort that metals are melted. And the beginning and the end of the art of the furnace lies in controlling temperature. During recent years, especially since the development of electric furnaces, there has been remarkable progress in the accuracy of this control, and the summit appears to have been reached in the appliance recently displayed at a scientific exhibition in London, England. The instrument is intended not only to keep a furnace at a certain temperature, but to raise or lower the temperature in accordance with any pre-arranged programme. In general appearance it is similar to a recording barometer, the pen tracing out a curve which rises and falls according to the temperature. A metal plate cut to a certain shape is laid over the chart, and if the temperature falls too low the pen comes into contact with the metal and completes an electrical circuit which operates mechanism arranged to raise the temperature of the furnace. Contrariwise, when the temperature gets too high the pen comes into contact with another part of the metal actuating mechanism for reducing the temperature. The curves of the metal thus determine the fluctuation in the furnace temperature.

Fig. 5.—Transportation truck with trailers.

Increasing Man Power Through Management

Placing of Employees According to Ability—Importance of Definite Instructions—Temperament Must be Reckoned With—Foreman Should Take Time to Plan Work—Leaders, Not Drivers, Make Best Executives

By L. W. OLSON

Factory Manager Ohio Brass Co.

WE ALL recognize that one of the most important functions of an executive is the management of his men. I have not tried to form any estimate of the proportion of his time to be so applied, but I know of estimates others have made placing this as high as 70 per cent. However, we are not concerned particularly with any mathematically correct proportion, which after all must vary with different lines of activity. Of the supreme importance of the task we are all agreed.

Distinguished by their methods, there are two types of executives:—Drivers and Leaders. The former class was perhaps more prevalent years ago than it is now, and it is certainly encouraging to believe that this is so, for it is a distinct mark of progress and advancement in industry. It is my conviction that plants managed by Drivers have higher production costs than those managed by Leaders. It is certainly not necessary to argue as to which method is the more desirable; for aside from the pleasure that comes from contact with a contented and co-operating force of men—there is that wonderful efficiency and economy that comes from loyal and contented people which no one can definitely measure, but which we all know exists.

It has been said that Leaders like poets, are born and not made. This is undoubtedly true to a large extent. We all know of glaring examples of individuals who are brilliant mentally, strong physically, clever, skillful and educated, who are wonderful in individual accomplishment, but who cannot manage other people. Even with a limited contact they always seem to rub everyone the wrong way. Then there is another type—pleasant, amiable, and well liked, but who, upon being given any authority over others seem to feel their importance to such an extent that they become unbearable. This is the type that are afraid others will not recognize them as boss, and think they must periodically do something that shows conclusively that they are vested with authority.

Real leaders need no special badge of authority, but naturally in an organization it becomes necessary to prescribe bounds and limitations, and to designate functions. Leaders are undoubtedly possessed of a natural inherent talent, which when developed to a high degree makes for prominent and distinct leadership. However, others may have less natural endowment but by persistent and intelligent application may so develop themselves that they succeed as leaders in a large measure.

Author delivered this talk to the foreman of factory he is connected with.

Development Necessary

Comparatively few people, if any, are so generously endowed by nature that no further development on their part is necessary, and many wonderfully gifted people have never made use of their talents nor would they work for their development, but their ambitions were satisfied with a proportionately small accomplishment. Not all of us have the ability of leadership given us in the same degree, but perhaps by careful scrutiny of ourselves, by attention to certain fundamentals, and by a persistent effort along certain lines, we may be able to improve the talent we have and develop it to its limit. No such development as I have in mind can come without hard work; but after all the harder the task and the more intense the application, the greater is the satisfaction that comes when accomplishment is complete.

I have set down the following as some of the cardinal principles involved in the management of men, and shall discuss each one separately.

Place each man according to his ability. Give careful, correct and precise instructions. Manage the individual according to his temperament. Delegate and supervise properly. Compensate fairly and proportionately. Set a good example. Maintain discipline.

Cultivate an unselfish desire to help your men. Develop your personal character. This is not perhaps a complete list, nor is the sequence perhaps according to exact relative importance, but it will serve my purpose.

In human management it is of utmost importance that each man be placed at the kind of work he is best fitted for. This means that you must carefully study the abilities and capabilities of all your people. Unless this is done misfits of all kinds will occur and you will suffer handicaps from the very beginning that will influence all subsequent management.

Careful and Precise Instructions

A great deal of misunderstanding and discontent is caused by a lack of proper attention to this factor. Nothing is quite so unsatisfactory to one who is anxious to carry out instructions as to have only a vague idea of what is wanted. On the part of someone who is looking for an excuse for his failure to accomplish a result nothing can more quickly result in an argument than ambiguous or insufficient instructions. If it is a piece rate task, or if the operator is really anxious to make a showing, he becomes discouraged and often leaves. If he is not conscientious it may make a very poor and indifferent worker of him. In the case of executives and their immediate subordinates, it may result in a woeful loss of time for the one, and discouragement for the other.

The executive cannot expect to be able to delegate work to a subordinate, and have him grow in ability to take assignments if that executive is not willing and able to instruct properly, nor would that executive have developed much himself if those whom he had been under had been negligent in this regard. If you are in the habit of giving insufficient and unsatisfactory instructions, don't be surprised if some day you get results that reflect rather markedly your lack of attention to this factor and which may react as a boomerang on your advancement and prospects.

We are all so different in our make-ups that we do not respond alike to the same influences. To some people praise is as necessary as food and periodically it must be supplied; others are absolutely indifferent to praise; while others are easily spoiled by too much of it; sharp reprimands are necessary in some cases and mild ones in others. While different circumstances call for different procedures, at no time is it necessary to become profane or abusive. The English language is flexible enough to express your mildest sentiments or your severest criticism. Above all things be considerate. It is far better to leave something unsaid than to be sorry for some spoken word, for even a subsequent apology does not take away all the sting.

Delegate and Supervise Properly

I have known executives of all stations who were extremely industrious, but who accomplished little. They were so busy doing things, they had no time to talk to anyone, nor to give any attention to their subordinates, except perhaps a favored few. They lacked personal balance.

I have known foremen who would set up every job; who would go to the tool room and get all the tools; who would go out of their way to make combinations and make-shifts, and yet their department would not be efficient. They would spend so much time getting a job started right, they would have no time to see it after that. They had no time to go over their orders, but would pick

them out haphazardly or they would be picked out for them of necessity. They had no time to plan their work, to judge their men, or to watch their product, yet they would work themselves into nervous exhaustion and fail in health.

They were so busy doing little details that they lost sight of the larger and more important things. They were so occupied that they had no time for conferences or interviews. They fooled themselves into thinking that the details they were doing could not possibly be done by someone else. One of the hardest things I have had to learn is—when to cease doing a detail and delegating it to someone, and I am still struggling with this problem. This is especially difficult when it involves things that I feel I can do exceptionally well myself, or things that I am fond of doing.

Principle of Balanced Application

To give to each of your tasks and duties just the right amount of time and attention, that its importance deserves is what might be called a balanced application. The man who expects to grow in executive ability must learn that his function is not to perform details, but to teach others, and then allow them to do them, giving just enough supervision to know that the work is being satisfactorily accomplished. The rapidity with which we can climb to higher positions or the speed with which we can make our present positions more important, depends almost entirely on our ability to master fully our present tasks; train others to do correctly and rapidly some of the less important things we are now doing and then to equip ourselves to lie in line for more important things that may be delegated to us from time to time, as our superiors go through the same process.

Many men are excellent delegators but very poor supervisors. They are quick to assign duties and tasks to their subordinates but have not learned to properly check after the assignment has been made. They supervise either too much, or too little. Sometimes they interfere unnecessarily. This robs the subordinate of his opportunity for initiative and only loads the executive with unnecessary detail. Such interference will stunt the development of the subordinate, and discourage him. I have in mind in a general way, relations existing between superiors and subordinates where initiative is to be developed. Obviously various kinds of assignments require different kinds of supervision and instruction; as for instance tasks in repetition production, should be very carefully and methodically planned and supervised. Even here too much, or interfering supervision may become irksome, and distasteful.

You may have been in the habit of doing a certain thing in a certain way. Don't for that reason alone, insist on others doing it the same way if satisfactory results are obtained by some other method, for some day someone will do it much better and more rapidly than you ever did, and it might be humiliating to you. We oftimes hear this: "I might as well do it myself as to try to tell someone else how and it will not be any harder for me, and it will be accomplished sooner, and to my entire satisfaction." Such an individual will always be doing it himself, and really confesses a lack of executive ability. Human natures and human abilities vary over such a wide range that there will always be some things which we cannot delegate without actual loss of efficiency and value and the problem for each individual to solve is what duties he should delegate and what duties he must preform himself.

Effective supervision demands on the part of the executive a thorough and complete knowledge of methods and results. Too often a subordinate is allowed to proceed without supervision until he has finished his task or until he has accumulated results of a considerable amount. You will find the results are not to your liking and you censure him for not having requested supervision when you yourself are at fault for not having furnished it. I do not mean to say that you cannot often judge by the results you are getting. In fact it becomes necessary sometimes to limit supervision to a judgment of results.

I wish to emphasize, however, that when you elect to supervise in this way you yourself take a risk and your criticisms of the result if adverse must be made in a spirit of suggestion and to be solely a guide for future procedure, and not as a criticism which might cause disappointment and discouragement, for you are responsible for the manner in which you elected to apply your supervision.

Compensate Fairly

If I should try to name the most important factor in making loyal and contented employees I should say a square deal in compensation. This does not necessarily imply the highest wages nor the easiest tasks, nor even a combination of the two. It does imply that all people get a reward commensurate with their worth or as near to this as is humanly possible. You will often find plants where compensation in the form of piece rates or day rates are exceptionally high in some or many instances, or where the average of all compensation is equal to or above th eaverage in other shops; nevertheless, on account of large and flagrant discrepancies in piece rates and day rates, there is a general feeling of dissatisfaction and uncertainty that makes for lower efficiency. Those enjoying the higher rates are fearful lest their seeming advantage be lost and those required to take lower compensation feel that they are not getting fair treatment.

On the other hand there are plants where perhaps through force of necessity the average compensation may be even slightly below the average of the community, but by painstaking diligence in pursuing a policy of fairness to all a higher degree of relative fairness in compensation is maintained and a much larger degree of general satisfaction and stability results. This particular phase of human psychology is a very sensitive one. Men naturally resent discrepancies in compensation that they feel are not justified and more trouble can come from inequalities in pay than from most any other one thing. In this connection two factors come to my mind:—An unbiased judgment based upon facts and prompt action to reward merit and eliminate discrepancies.

It is no easy matter to judge values and interpret them into terms of compensation. It is least difficult where all are doing the same class of work on the same product but becomes increasingly difficult where the number of classes increase and where the character of the work becomes widely different. It is no easy matter to judge as between different kinds of skill; between skill and physical strength; between intense application in a repetitive operation and painstaking care in delicate manipulation; between executive responsibility and the application of a highly trained mind to more or less intangible problems. No rules can be laid down for procedure or even guidance, so we can only use our best judgment. One thing is certain, he who can best satisfy the largest number of different individuals of different accomplishments excels in the application of this factor.

Be Consistent in Rewarding

The second phase of this factor is to take the initative in rewarding merit. Do not confine increases in compensation to those who are most insistent and pester you. Know their worth and value in the organization, and take steps that will secure for those who deserve it a just and prompt recognition in the form of increased compensation whenever you have such adjustments to make. Get in touch with that branch of your organization having jurisdiction over such and if conditions do not justify it at the time you would desire to secure action, you can at least discuss your desired recommendations and perhaps obtain authorization that will enable you to go back to the man, commend him for his performance and make him a promise that he can look forward to. The management of this company has never retracted on promises made by foremen, to their men, or by other executives to subordinates where there was shown an honest attempt to judge fairly. Remember that a small increase voluntarily given is more effective and gives more lasting and better satisfaction than a larger increase secured by threats or coercion, to say nothing of your own feeling in the matter, and the effect it will have on your own peace of mind.

If at all times you carry with you a real desire to help, you will quickly see many rough places made smooth. This is not only true of your department, but of life in general. A wise man once said: "I will try to point the way of success to others and by showing it to them, I

(Continued on page 29)

Machine Wear Affects Quality of Product

Machines Must be Properly Installed and Accurately Aligned—Shocks Should be Minimized—Sag of Parts—Selection of Materials—Effect of Twist in Bed—Strains Caused by Cutting Tools

By FRED HORNER

THE detrimental effects resulting from wear are more serious in the case of machine tools than they are in the majority of prime movers, and mechanisms such as pumps, cranes, etc. A certain degree of looseness in these is sometimes of no consequence, beyond the noise produced, and a slight want of alignment or concentricity means no more than increased friction. The precise testing and re-adjustment of a great many of such mechanisms is therefore not attended to in the same way that corrections of machine tools are, the chief aim being to secure free and quiet working. But a machine tool may work with the greatest ease, and quietness, and yet be almost useless for performing its proper functions. This is because it is a reproducer of shapes in most instances, and the accuracy of alignments, of planes, of parallelisms, of angular settings, etc., vitally affects the work produced. Hence, the means for preventing, restricting, or minutely compensating for wear is of first importance, and the methods of accomplishing this often differ essentially from the compensating devices adopted in ordinary mechanisms. What makes the matter so difficult is the variance of movements, such as the lengths of strokes or sliding actions, which are frequently lengthened or shortened according to demands; therefore, the wear is not uniform from end to end, say, of a slide-way, and this brings in annoying difficulties. The directions of cutting pressures also vary in different machines, and on different kinds of cuts in the same machines, and the means for combating effects of wear have to be designed accordingly. The features of design and the best selection of suitable materials of construction also have an immense influence on the degree of wear that develops.

Wear, when it is legitimate and unavoidable, can nevertheless be controlled and arranged in such a manner that the machine continues to evolve a product within the limits of inaccuracy desired. The wear proceeds on well-known lines, and is kept within control in such a fashion that either no corrections are required for long periods, or these are effected in a simple way by provisions incorporated in the construction.

The first thing that determines the lasting accuracy of some kinds of machine tools is the nature of the foundations. Tables and beds, especially the larger ones, wear according to the way in which they are supported; that is, if an apparently rigid casting is supported on the twist, or the foundations alter (and are not put right) and produce the same result after a short time, the wear of the super-imposed slide or table takes place accordingly (across corners) and gradually the sliding motion partakes of a helical path, more or less accentuated as the load varies. Further settlements in the foundation may improve this fault, or increase it; but usually corrective measures are difficult after a period of running on a twisted bed and the only remedy is refacing the slide surface. A long bed that sags likewise develops uneven wear, the dropping portion giving difficulty in maintaining a true plane of movement, and in setting up gib strips effectively. The overdoing of wedging-up may bring another trouble, that of humpiness at one or more spots, which will cause bad sliding, and uneven wear. When practicable, the principle of the three-point support ought to be followed, so as to let the plane surfaces remain unchanged even though the floor is not true, or becomes altered.

Strength of Framings

The next important feature governing wear is the relative strength and rigidity of frames. Weak sections, insufficient thicknesses, and lack of proper staying and ribbing allow flexure to arise, in varying quantities according to the bulk of the work, or the severity of cuts. While a frame is thus in a state of flexure the slideways and the spindles do not stand in the same relations that they occupy while the machine stands idle, consequently the wear on the moving parts is indeterminate in direction and amount. This difficulty is especially marked in the case of machines which carry heavy overhanging loads (such as shapers and column-and-knee millers) the cantilever action of the load (which may include heavy vises or fixtures) being such as to flex a frame and bulge it, unless there is plenty of inherent strength in the casting. Weak framings further induce another trouble—vibration—which, apart from its ill effects upon the cutting processes, usually increases wear unnecessarily, and produces a peening action under certain circumstances, an action that gradually deforms machine parts, and makes them wear in strange fashions.

Weak Tables

A secondary slide that is unduly weak will give rise to trouble from flexure and shake, but a main work table (or a tool saddle) suffers further difficulty, from the load imposed directly on it. The problem is most strenuous in regard to tables which sustain massive castings, or heavy jigs or fixtures. Two things may happen if the table is thin, or improperly stayed. One is that it may sag towards the extremes of movement, the other that it will assume a deformed outline when heavy objects are bolted on it. Such conditions can happen in respect of planer, milling machine, or boring machine tables. The question of sag is however partly dependent upon the support afforded by the bed below.

Proportions of Slideways

In some machines—lathes for example—no question of end overhang from the supporting slide-way arises, but it does in the types of tools mentioned in the preceding paragraph. Hence the problem of sag is brought in, and also the question of local wear, due to incorrect proportioning of the supporting way in relation to the superimposed table. Good practice in planing machines is to make the bed about 1¾ times the planing length in the smaller machines, and about double the planing length on large sizes. The over-run on a small machine might therefore be about that represented in the diagram, Fig. 1. Yet the resistance to sag, and truth of wear depend largely on the inherent strength of the table casting, and practice of late years has tended towards the adoption of box tables, strongly ribbed, where hitherto tables open underneath and ribbed only were employed.

The proportions of slide-ways as they

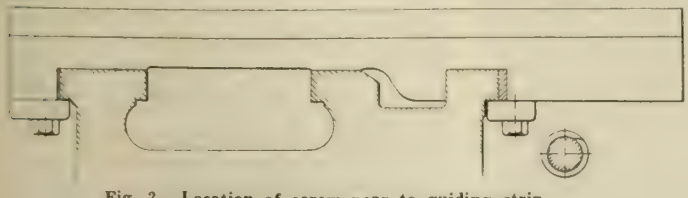

Fig. 2.—Location of screw near to guiding strip.

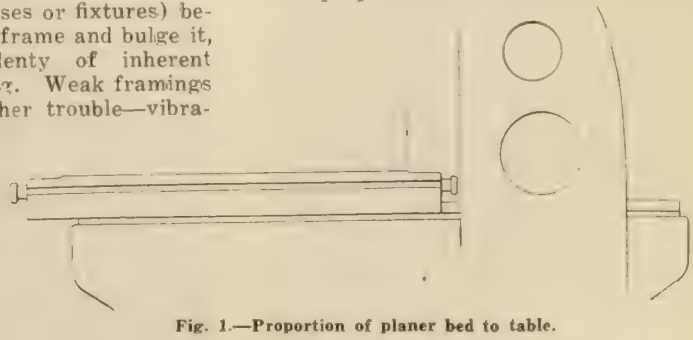

Fig. 1.—Proportion of planer bed to table.

affect tool-rams concern the flexure of the rams at extreme points, and the evenness or otherwise of the guideways. Some rams are wholly supported at all parts of the stroke, others are unavoidably projected quite a distance in order to reach over the work, and the quality of the wear varies at different parts of the stroke, being much more severe and localised at the extreme overhang point than when working well within limits. A shaper ram, as a case in point, wears more rapidly at the front of its bearings than elsewhere, and the side pressure is very severe. Therefore, a single long taper invariably is not suited for taking up wear in cases such as this, a gib with several screws set up according to needs being often preferable. In certain instances overhang of rams is lessened by the inclusion of supplementary slides, that can be adjusted to sustain the ram as close as possible to the work; this is done in some slotting machines, and besides lessening the springs, helps to reduce wear, especially localised wear.

Auxiliary Sliding Ways

When it happens that the excessive loads on a slide are only infrequent or its movement is very brief or occasional, there may be no necessity for the employment of full length or full width ways. The practice in these examples is often to sustain the overhang of the slide upon auxiliary guide faces (or perhaps rollers) using the normal width bed for ordinary guidance, a method common in some boring machines, and planers. Or the design is arranged differently, using a prop or stay mith narrow slide surface, or roller.

Wear Across Corners

In addition to the circumstances already noticed which induce irregular and localised wear, another condition has to be observed, namely, the effect of the twist imposed by the propelling medium of the slide—whether screw, rack, chain, or lever. Some lever actions produce an uneven thrust which may make a ram or slide go harder at certain locations. And nominally direct pulls or thrusts with screws, racks, or chains may not be really satisfactory, because of their distance from the spot where the resistance (tool or work) lies.

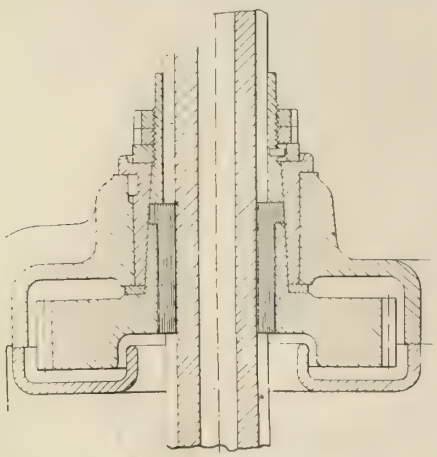

Fig. 3.—Bush to relieve side pressure from spindle.

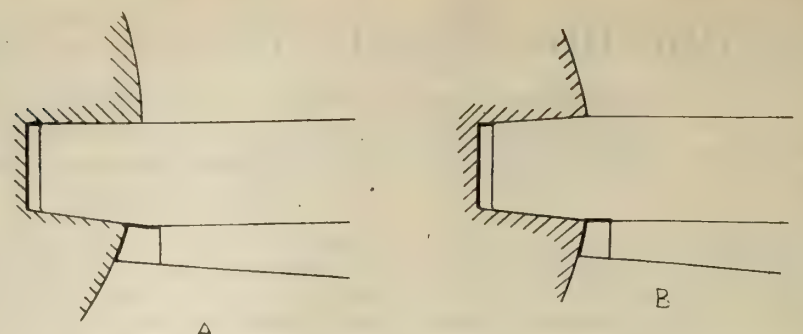

Fig. 4.—(A) Good type of index bolt. (B) Type that wears badly.

What happens in this latter event is that part of the slide nearest the screw or rack starts off, and the remainder follows reluctantly, as its movement is opposed by the cut. An incessant strain becomes imposed on the slide, which twists, and besides working stiffly, wears across corners. The "narrow guide" principle has done much to lessen this trouble in many types of machine tools, since the control of the slide movement is brought within narrow limits, and these lie close to the propelling medium, such as illustrated in Fig. 2. Some specimens of slide motions cannot be actuated with a single screw, owing to their unavoidable spreading of guiding ways, and the screws or racks need to be duplicated, and kept in adjustment to work in unison.

Local Wear on Long Slides

This is always a source of difficulty in machines that must undertake work of varying dimensions, the lathe carriage being the most prominent example. In general work, as distinct from lathes always employed on long sliding or screw-cutting movements, there is more wear near the headstock, affecting the carriage ways, and the screw. This entails inevitable difficulties soon or later, from loss of alignment of the slide movement, and irregular working of the screw. The trouble is enhanced if unsuitable materials are employed in construction, say a harder carriage than bed. The correct way is to have harder surfaces on the bed than on its sliding element, throwing the wear on the latter, and preserving the truth of the bed as long as possible, a dictum which is reflected in the use of semi-steel castings in some instances, and in chilled or densened guide ways in others. The employment of nuts softer than their steel screws also acts beneficially.

Increase of Wearing Surface

A factor that has had to be revised from time to time in machine tool design is the proportioning of wearing surfaces, alike in slides and rotating elements. The small areas of contact that sufficed in the early machines, and which were suitable because the work was light, and the labor of preparing the meeting surfaces also suited the primitive means then available, needed to be increased as the power of cutting developed. And then, when rapid-cutting steels altered practice so radically, considerable enhancements of slide areas and of spindle diameters and lengths were inevitable. Even lately the regular vees of the American type of lathe have been found wanting in durability and sustaining power, and several modifications exist where the front vee is enlarged, or altered in profile, or is supplemented by flat edges to assist its controlling and wearing capacities.

The policy of placing additional bearings to support shafts that were formerly allowed to overhang at one end accounts for the prevention of unnecessary wear, not merely on the shafts but also to pinions subject to irregular wear on the teeth when not kept well in mesh. The "whipping" of shafts and spindles is also eliminated by extra bearings, the chief function of which consists in the preservation of alignment. A similar idea is adopted when long lead or feed screws are in use; these, if not sustained at appropriate locations, would sag, and the consequent wear would be uneven as the nut had to take out the sag in its passage along the screw. Cut-away bearings or tumbler bearings are of necessity fitted, so that the central axis always remains in the same plane.

Another specimen of improved bearing design is that seen in types of drives where a spindle has to slide through a pulley or gear, and the side pressure due to the drive is best relieved from the spindle to prevent its premature looseness in the bearings, as well as to render the sliding action free. The pulley or gear sometimes runs on an extension of the frame, or in a bush fitted therein (Fig. 3); or mayhap an internal bore is utilised to journal the hub of the pulley within, using either plain surfaces, or ball or roller-bearings.

The Effects of Shock

Several classes of shock are met with in machines of one sort and another, the results of which include premature wear to slides, bearings, gears, belts, clutches, etc. One of the ordinary occurrences is that of intermittent cutting, on lathes and planers, the tool cutting metal and wind alternately, with bad consequences to the slides, the feed arrangements, the belts and the gears. A careful selection of tools most suitable for the job is essential, so that the edges shall not plunge into the cut with too much avidity and leave it with a violent jerk. Sometimes it is also feasible to arrange two pieces of work or two gangs in such fashion that the operation of a pair of tools is staggered, and the lathe drive or the table drive suffers no strong shocks, one tool being engaged when the other is missing.

Reduction of shock at the moment of reversal is likewise an imperative necessity, and is sought in planers, gear cutters, etc., in the form of spring buffers, or air-cushions. What occurs when the tool enters and leaves the cut is a matter dependent in some degree on the actuating mechanism in the case of shapers, and certain types of mechanism possess the merit of a gradual start and gradual termination of the stroke, which lengthens the life of the tool as well as reducing wear on the machine parts from shock.

An especially vital part of some machines is indexing mechanism, which may or may not be subject to shocks, a question which depends on speeds, mass, and the proper design of the parts. Nominally, in turrets there ought not to be shock as the index-bolt catches into place each time, but it all depends on the speed of operation, the working condition of the parts, and in hand-operated machines on the human factor. In order to gain a more powerful control of the index action, the index ring should be as large as practicable, an advantage which persists during the cut by keeping the tool steady with less strain and wear on the mechanism. In simple index-bolts for turrets the best procedure is not to form the bolt end with a double taper (with the idea of exact positioning) but to make one side straight so that the turret is swung round the straight side of the bolt will come slap against the index notch. The turret can then advance no further round, and the bolt slides home quietly, Fig. 4, A. On the contrary, with the double taper bolts, B, the turret may swing too far, the taper then has the duty of forcing it back a part of a revolution before home is reached, a duty that does not tend to do the parts any good.

Some turret index recesses are made in the form of bushed holes for pegs, instead of notches. This mode of construction offers a certain advantage, that is, when the bushes are worn out of accuracy, they can be replaced, and the original state of the holes in the turret not being affected ensures accurate pitching of the new bushes.

Wear of Screw Threads

Threads are usually subjected to severe frictional pressure, or to strong pull which deforms the sectional shape. Vee threads get thinner, or they assume a buttress shape, and square threads become narrowed. Local wear creates a difficulty in any case, for the nut cannot bear equally on the worn and the good parts. Hence it is better to wear the nut more rapidly than the screw. A useful practice in regard to heavy end pressures is to anticipate events and cut a buttress thread instead of a vee, so that the lateral pressure will occur against the vertical face, side thrusts will be prevented and the sectional area of the thread will be well sustained by the slope of the buttress. Unfortunately, it is in many instances necessary to be able to feed both ways with equal facility, and the buttress is therefore barred.

There are two or three methods of reducing unnecessary wear on threads, one useful device being applied to threaded parts which have to be removed and replaced often. Pilot or plain sections are used as extensions before or beyond the thread (or both) and serve to steady it in alignment while the screwing up or unscrewing is done. This likewise applies in some kinds of short screws, which are not separated—as chucks and face-plates are—but which nevertheless have to withstand hard service. The employment of counterweights also in the balancing of heavy masses which slide up and down columns greatly lessens the wear of screws, especially those in use for feeds, such as in vertical planers.

Avoidance of Unnecessary Wear

Since the introduction of gear drives and feeds greater attention has had to be paid to the restriction of unnecessary wear, from the multiplicity of parts that are involved. It is an expense to keep numerous bearings constantly running and supplied with oil, a fact that also refers to loose wheels, and to the teeth of gears. Noise develops more rapidly with wear in the last-named case, and the policy should be to have only those shafts, clutches, and gears revolving that are essential to the drive or feed in use. And on high speeds the fewer gears in action the better.

Some part of this problem is a question of the best selection of machines for specific functions, and a large works may be in a better position to purchase machines exactly fitted for certain operations, and thus avoid the complications of a wide range of movements needed for more general purposes. An interesting example of this matter is that of high-speed light drilling machines, particularly those of extended radial type. Years ago it was usual to do the small holes on an ordinary radial of gear-drive type, the high speeds (though not high enough for the size of drills) being attained at the expense of great clatter and noise of the gears. Then the sense of the abolition of gears altogether for this class of drilling was evident, and a special light class of radial sensitive rapidly developed. A similar kind of change is taking place in regard to certain other machines possessing specialised functions, and embodying simplified designs with the minimum of gears and bearings.

Trouble With Thin Sections

A special class of trouble from wear is encountered in regard to thin sections of metal, such as those in collets and other shell-like objects. These with constant use are liable to suffer deformation, especially if not designed with correct proportioning of metal in the various portions. The shape slowly becomes modified, the fitting instead of wearing regularly is affected by the deformation, and gets out of true concentrically and longitudinally. Sometimes the fault arises from too great disparity between jaw parts and the tube part, or from over-strain in trying to grip too hard for the capacity of the collet. Or it may proceed from lack of efficient support in the contractile element, which allows the collet to warp and spring each time it is used.

The split bands of friction clutches are similarly liable to change of shape, gradually getting out of the original form imparted to them. This makes trouble by reason of the high spots rubbing in or on the friction surfaces, and causing noise, or tending to let the clutch engage when it ought to be free. The sensitiveness of the engagement is naturally interfered with, and the lever movement may have to be extended to get the band well out of contact. Th fault either arises from poor design, that is thinness, or incorrect proportioning of the parts, or from too severe service imposed.

Application of Hardened Parts

Apart from the employment of steel castings, or semi-steel, or of chilled ways, there is an immense range of fitments where the wear is only local, and not along broad or long extended areas. The choice in these has to be made between case-hardened and full hardened parts, the one being sometimes suitable, the other maybe imperative. Case-hardening does not always satisfy requirements, partially because it is only good for a limited amount of wear, and because also it will not withstand deformatory action well, being compressed into the softer metal beneath too easily under hard pressures or blows. But a measure of economy is available in many instances by screwing or riveting or welding on hard steel facings or tips to articles subject to shocks, and so also allowing for convenient renewal from time to time.

Importance of Clean Surfaces

Many a good slide or bearing has suffered damage through carelessness in lubrication, or from access of grit that ought to have been excluded. The danger is naturally more likely in the faster movements (such as shafts) where a few specks of grit may immediately produce scoring seizure, and possibly ruin a journal and brasses, than it is in a slow-moving slide. After all possible care in the selection and the filtering of lubricating oil, and the adoption of dust guards, felt pads, etc., there remains a possibility of accidental creeping in of grit. Therefore, bearings, and if possible, slides, ought to be constructed with provision for the escape of foreign substances into catching grooves or corner spaces, where they remain undisturbed until the time comes to take the elements apart.

Difficulties of Efficient Lubrication

In some kinds of machine tools there is great pressure imposed on bearings or slide-ways, from the weight of work, or the thrust of the cut, or both combined, and it is essential that a film of oil shall remain between the rubbing surfaces. Otherwise wear is bound to occur rapidly, and perhaps to the early

(Continued on page 29)

Designing Screw Threads for Bolts and Nuts

Bending Stresses—Stripping of Threads—Failure Due to Shear—Effect of Vibration—Locking Devices—Size of Lock Nuts—Axial and Radial Thrust—Opposing Forces

By L. T. RUTLEDGE

IN the issue of Feb. 23, consideration was given to the design of machine screws and bolts, and this feature of tool construction is continued in this issue.

For small screws and bolts, the above stresses depend pretty much upon the judgment of the mechanic and it is quite useless to attempt any accurate calculations. Every mechanic knows how easily the head can be twisted off a cap screw, so it is apparent the stresses set up in this manner are of considerable importance and must not be neglected where great accuracy of design is involved.

(b) Stresses due to external forces:—As a general rule, external loads may produce either of two direct stresses, namely, tension or shear. An example of a load producing tension was given in lesson 4 on "Eccentric Loading" in the analysis of stress in the holding down bolts of a radial drill.

Assuming that a certain steady load "P" produces a direct tensile stress in the bolt or screw and as the section at the root of the thread is the minimum section, then it is evident that the area at the root of the thread must be the one considered and it must be such that the stress does not exceed the permissible value set forth in the working specifications. If d_1 is the root diameter, then the following equation applies:

$$d_1 = \sqrt{\frac{4P}{\pi S_t}} \quad ---(38)$$

Should the bolt be subjected to a shearing stress instead of a tensile one, then a similar formula applies with Ss substituted for St.

(c) Stress due to Shock Loads:—In some classes of machinery the bolts have to be designed to resist shock loads. The stress induced by a suddenly applied load is at least twice as great as that produced by a steady load. The energy of a suddenly applied load must be absorbed by the bolt. The measure of the energy is the product of the induced stress and the total elongation of the bolt. As far as the mathematics is concerned, it is obvious, that the product may be constant and yet the factors giving it may be varied. This very feature is made use of in creating a condition under which the bolt will be less liable to fracture under a shock load. If the elongation is permitted to increase then the stress must diminish. It is understood that failure occurs when the stress reaches a certain value. There are two simple ways of accomplishing this design, namely, making it possible for an increased elongation without a decrease in strength as follows:

1. Turn down the body of the bolt to the same diameter as the root of the thread which is quite permissible, because, as stated above, failure under stress will take place at the smallest section.

2. Instead of turning down the body of the bolt, its cross-sectional area may be reduced to the area at the root of the thread by drilling a hole up the centre of the bolt from the head end to a point quite close to the end of the thread.

Fig. 30 illustrates the two methods suggested. Actual cases are on record showing how failure was prevented by either of the above methods. Let this point be emphasized, namely, the one bolt is just as strong as the others, since each has the same minimum section but the lighter bolt will stretch more than the heavier one under the same shock load and be less liable to fracture.

(d) Failure due to Thread Stripping:—As previously suggested, a bolt may fail by breaking off at the root of the thread where the sudden change in the cross-section occurs.

$$W = \frac{\pi d_1^2}{4} S_t \quad ---(a)$$

Where w=the external load and d_1= the root diameter.

2. A bolt may fail by the threads stripping on the bolt or in the nut. The stresses on the threads are bending and shear. A section of a thread is shown in Fig. 31. Assume the load w to be uniformly distributed over the surface of the thread. Let

N=number of threads in the nut.

B=total length of thread in the nut being the circumference of 1 turn, it being considered as a circle.

The thread partakes of the characteristics of a cantilever beam. The maximum bending moment for a beam of this type, fixed at one end and uniformly loaded is

$$\frac{WL}{2} \quad ---(b)$$

The resisting moment, by the flexure formula for beams equals

$$M = S_b \times \frac{I}{C} = S_b \frac{bh^2}{6} = \frac{S_b h^2 \pi d_1 N}{6} \quad ---(c)$$

where S_b is the flexure or bending stress.

For equilibrium the resisting moment equals the bending moment then equation (b) equals (c) or

$$\frac{Wl}{2} = \frac{S_b h^2 \pi d_1 N}{6}$$

$$\text{or } W = \frac{S_b h^2 \pi d_1 N}{3l} \quad (d)$$

Equating equations (a) and (d)

$$\frac{\pi d_1^2}{4} S_t = \frac{S_b h^2 \pi d_1 N}{3l}$$

$$\text{therefore } N = \frac{S_t}{S_b} \times \frac{3l d_1}{4h^2} \quad (e)$$

If St be taken equal to Sb then

$$N = \frac{.75 l d_1}{h^2} \quad (39)$$

which is a general formula for the number of threads necessary so that stripping will not take place.

For U. S. standard threads, h=⅞ p and l=0.65 p, where p=pitch.

Then by substitution in (39)

$$N = \frac{.75 \times .65\, p d_1}{(.875\, p)^2} = \frac{.638 d_1}{p} \quad (40)$$

Next, consider failure due to stripping from the standpoint of shear.

$$\text{Area in shear} = \pi d_1 h N$$

$$W = \pi d_1 N \left(\frac{7}{8} p\right) S_s$$

Equating the equation immediately above with equation (a) we have

$$\frac{\pi d_1^2}{4} S_t = \frac{7}{8} \pi d_1 N p S_s$$

$$\text{therefore } N = \frac{S_t}{S_s} \times \frac{d_1}{p} \times \frac{2}{7}$$

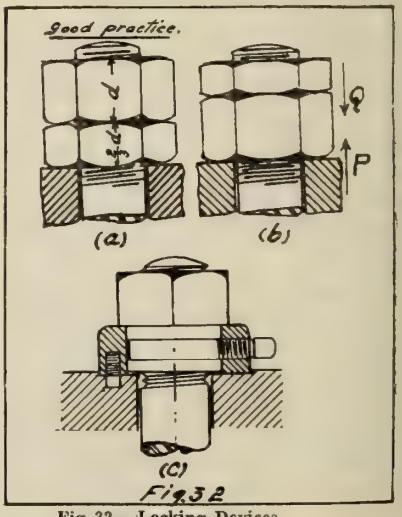

Fig 32.—Locking Devices.

The author is Professor of Mechanical Engineering at Queen's University, Kingston, Ont., and should any reader wish help in any problem on mechanical matters, write us, and we will see that Mr. Rutledge supplies you with the desired information.

and if St be assumed equal to Ss then

$$N = \frac{.357 d_1}{p} \quad (41)$$

Comparing equations (40) and (41) it is apparent that the thread is $\frac{}{.357}$ or 1.78 times stronger in shear than bending. So that in designing against stripping only bending needs to be considered. Where accurate calculations are required equation (1) above should be used in preference to (40). In practice, however, almost twice as many threads are put in the standard nuts as are theoretically required.

Locking Devices

Even though bolts are fastenings that admit of dis-assembling with comparative ease, nevertheless the bolt must be a rigid fastening under service. The next must remain in position without coming loose. In machines where vibration exists, it is almost an impossibility to keep a nut on the bolt without some extra device. This appliance which secures or locks the nut, is called a locking device. The more common locking fixtures in use are the lock or jamb nut, collar nut, castellated nut, split nut, spring wire lock, spring washer, copper washer, set screw and other devices.

Automobile manufacturers use the spring washer and castellated nut with a split pin more than anything else. In high class construction the collar nut as shown in Fig. 32 is used. A headless set screw makes an excellent locking device if it is placed in a position parallel to the axis of the bolt and located half in the bolt and half in the nut. In assembling, it is best to thread the nut on its bolt up tight in its final position. Then drill, if necessary, with an electric drill, a hole in the thread as suggested. The best results may be obtained if the set screw is unhardened, because then the line between the set screw and the other members may be centre-punched which affords extra resistance.

The oldest design of locking device is the use of a lock or jamb nut. This method is also the commonest and cheapest one. In most cases the locking nut is smaller than the regular nut which is supposed to take the axial load put upon the bolt. A question might here be asked: "Should the small nut be placed under or on top of the main nut?" Many arguments over this very detail have taken place in machine shops. The following analysis, due to Weisback, shows that conditions may arise when the first arrangement would answer, while, for other conditions, the second arrangement would be the proper one to use.

In the analysis we assume that the lower nut is screwed down tightly against its bearing surface and that the upper nut is threaded down against the lower nut so tightly as the size of the stud or bolt will permit. As shown in Fig. 32, let the pressure between the

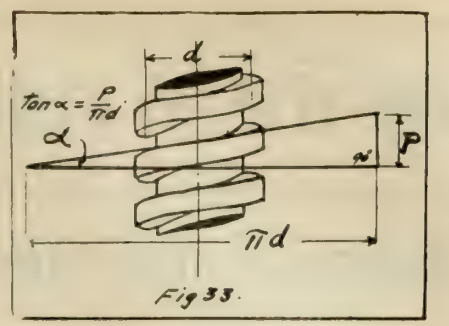

Fig 33.

Square Thread Data

machine surface and the lower nut be P and the pressure between the two nuts be Q. In 32 (b) where the jamb nut is the smaller one, and is on top let us consider the forces acting. It is apparent that the force Q acts downward whereas P acts upward and the resultant force is (P-Q) in magnitude and it acts upon the threads of the stud. If P is greater than Q, the resultant acts upward. This means that the upper surfaces of the threads in the lower nut come into compression against the lower surfaces of the threads on the stud. From this it follows that where P is greater than Q, the lower nut must be of standard thickness as shown in 32 (b), since it alone must support the axial load on the stud which is extra, of course, to the pressures P and Q.

Now considering the case where Q is greater than P, it is obvious, the resultant force on the threads of the stud is downward, thus making the lower surfaces of the thread in the lower nut bear on the upper surfaces of the thread on the stud: hence the upper nut must be taking the axial load and for that reason should be of greater thickness, that is, it should be of standard thickness. Now if P were exactly equal to Q, the resultant would be zero. In that case, no bearing pressure due to tightening of the nuts would exist. The axial load alone has to be withstood by the nuts. For this condition, a little consideration will show that the nut of standard thickness should be on top as illustrated in 32 (a). It will be required to withstand the axial load.

In ordinary practice the quantities P and Q are unknown. If the designer has to select either of the two arrangements, the probability is that the one shown in 32 (a) would suit the conditions. General practice is to put the nut of standard thickness on the top. Instead of having the small nut half the thickness of the larger one, it is better practice to have it two-thirds the thickness. Nevertheless, though the arrangement of 32 (b) is theoretically incorrect, it is practically convenient. Very often the two nuts become so sealed together that a great force is necessary to separate them. When the smaller nut is on the outside less force is necessary to effect a separation.

Efficiency of a Screw

The screw is a simple application of the inclined plane, the thread on the screw fulfilling the same functions as a plane on the same angle. Consider a square threaded screw as illustrated in Fig. 33. The mean diameter of the thread is d, the pitch is p which is the axial distance that the nut rises in one revolution. The inclined plane equivalent to one turn of the thread is shown superimposed on the elevation of the thread. The horizontal length of the plane is

$$\pi d,$$

being one circumference of a circle of diameter d. Let

$$\alpha (alpha)$$

be the angle of slope of the plane.

$$\frac{p}{\pi d} \qquad \phi (phi)$$

Is the trigonometric tangent of this angle.

In the actual case, friction between the thread of the screw and the thread of the nut exists. This opposing force is equivalent as far as work is concerned in increasing the slope of the inclined plane. The additional angle is usually denoted by the Greek letter

$$\phi$$

so that including friction the condition is the same as if the angle were

$$(\alpha + \phi)$$

the tangent is the coefficient of friction denoted by the symbol

$$\mu (mu) \qquad \mu$$

Values of pi for different combinations of substances are given in the handbooks.

Let W be the weight lifted by the screw as would be the case with a screw jack. The useful work done per revolution of the nut without friction is force multiplied by distance equals

$$Wp = W\pi d \tan \alpha \quad (41)$$

With friction, the force to be applied at the mean radius of the thread to raise the nut is (say)

$$Q = W \tan (\alpha + \phi)$$

The total work done in turning the nut through one complete revolution is again force x distance equals

$$Q\pi d = W\pi d \tan (\alpha + \phi)$$

Then the efficiency when raising the weight—useful work divided by total work done

$$\frac{W\pi d \tan \alpha}{W\pi d \tan (\alpha + \phi)} = \frac{\tan \alpha}{\tan (\alpha + \phi)} \quad (41)$$

Formula (41) is the expression for the efficiency of an inclined plane or wedge. Any textbook on elementary

News From the Welding Field

Welding Non-Ferrous and Dissimilar Metals

Use of Puddling Hook—Avoid Over-Heating—Distribution of Flame—Proper Fusing of Added Metal—Increasing Tenacity of Copper Weld—Critical Temperatures of Nickel—Resisting Properties of Monel Metal

By FRED. E. ROGERS

METHODS of welding cast and malleable iron were dealt with in a previous issue and non-ferrous metals and dissimilar metals will be discussed in this article.

Welding of Aluminum

The oxy-acetylene torch provides the most practical means of uniting aluminum parts. Because of the avidity of aluminum for oxygen it is practically impossible to solder it or, if soldered, to insure non-separation of the soldered joints when exposed to corrosion. Numerous aluminum solders have been exploited and while some are fairly successful, it is recognized that soldering is not generally a dependable process, and it is not recommended when feasible to weld. A welded aluminum joint is dependable and when correctly made is as strong as the original section. It might be said that gas welding is the one method to be used for repairing broken aluminum and for jointing parts in manufacturing.

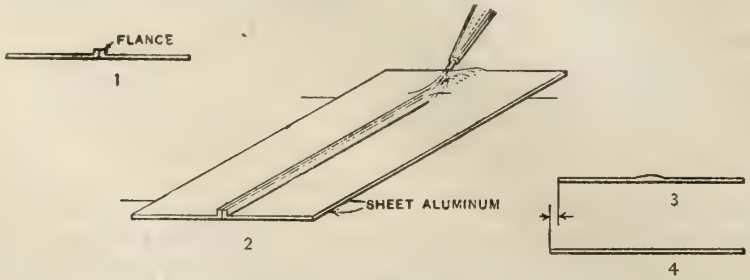
An aluminum casting and a rolled aluminum sheet differ in physical structure the same as cast iron and steel. Cast aluminum up to ¼ inch thickness or even more is generally welded without beveling the joint, using an iron puddling hook and spoon to break down the molten metal and to eliminate the oxide. As before stated, a slightly carbonizing flame should be employed when welding aluminum to reduce as much as possible the oxidizing action of the atmosphere. Cast aluminum sticks of special composition free from foundry sand and other foreign substances only should be used when welding cast aluminum, the puddling hook providing means for eliminating oxide and securing a sound weld, but D-B Matchless aluminum flux may be used to good advantage, and is recommended. It reduces the oxide and makes the use of the puddling hook unnecessary or reduces it to a minimum. A smoother joint will result when using an approved flux than when puddled, and this is important in many cases.

Weld from right to left when working on unprepared joints and using the puddling hook. Care must be taken to prevent overheating the puddling hook as iron oxide will be dissolved into the aluminum with consequent weakening effect.

Heavy aluminum castings should be grooved or beveled the same as cast iron, and then welding should proceed from left to right. The use of flux on prepared aluminum joints is urgently recommended. Better conditions will be obtained both in the structure of the weld and in the external appearance. Aluminum melts at about 1,200° degrees F. and welders are cautioned in preheating to avoid overheating a casting and causing a collapse. The temperature should never exceed 700 or 800 degrees; the proper temperature can generally be determined by rapping the casting with a stick while being preheated. A cold aluminum casting should give forth a metallic sound when struck as it becomes hot the metallic sound becomes less and less and when the safe preheating temperature has been reached or exceeded it will no longer resound when hit. Another test is the use of a pine stick. Heat no more than required to char or ignite a piece of fat pine stick brought into contact. Preheating is essential to avoid severe expansion and contraction stresses and also to conserve gases. The metal conducts heat rapidly, and unless preheated the welder may experience difficulty in maintaining the requisite welding heat although the metal melts at a comparatively low temperature.

It is advisable in the case of motor car crankcase castings which are thin and often of complex shapes to support the casting beneath the crack with sheet iron bent to fit the interior and covered with sheet asbestos. The sheet iron in turn may be blocked up with a brick to provide the needed support when the metal is hot.

Rolled aluminum, especially the thinner gauges are prepared for welding, preferably by flanging the edges to an angle of 90 degrees, the flanges having a height of 3/32 to ¼ inch, varying of course with the thickness of the metal. The flanges are fused together using Neapolitan flux to elimate oxide. Exercise care to avoid breaking down the metal and fusing holes through thin sheets. The effort should be to melt down the flanges making a perfect union and to pile up the metal at the joint. The joint is then finished with a planishing hammer, being beaten until of the same thickness as the sheet. In this type of welding no adding material is required but when butt welding aluminum sheets, drawn aluminum or wire adding material and flux should be used.



Aluminum Container Welding

Aluminum containers such as canteens, teapots and household articles are welded with the torch, using aluminum flux. The parts are drawn and formed with lips or flanges about 1/16 inch wide which furnish the filler material required in the weld. In the case of the canteen shown, the halves are held together in a revolving jig while being welded.

The speed of rotation and stopping and starting are controlled by a foot pedal. The edges of the part are dipped in Neapolitan flux preparatory to welding. Women operators are readily trained to do such light welding.

Welding Copper

Flame adjustment for welding copper should be the same as for steel but a larger tip and flame must be employed

Welding thin aluminum sheets.

for copper than for steel of the same thickness, owing to the greater radiating property of the copper. For instance, the No. 6 tip recommended for welding steel of 5/16 inch to ⅜ inch thickness should be used on ¼ inch copper or, putting it in another way, use tips of from one to two sizes larger on copper than on steel of equivalent thickness.

The torch should be manipulated the same as when welding steel except that it should not be held so close to the metal. Copper melts at a temperature of about 1,900 degrees F. and not so great concentration of heat is required. The aim of the welder should be to distribute the heat over a larger area, holding the point of the flame away from the metal.

Only pure copper rods should be used for adding material and D-B Anaconda rods are recommended for all copper welding, being the purest copper obtainable. The adding material should be fused by the heat of the puddle and the radiated heat of the flame, and care must be taken to secure penetration. On account of using a larger flame and a broader distribution of heat the welder may experience some difficulty at first in breaking down the side walls and localizing the puddle because of the larger areas affected. The principle of welding, however, is the same in all metals and it is a matter of some experience and practice only to secure sound work in copper.

Preheating is necessary when welding large copper sections, and is desirable in most cases in order to save gas and reduce the time necessary for welding. Preheated copper parts should be covered with Vulcanite asbestos and the welded seam should be protected with the same material from drafts and rapid cooling.

A welded copper joint is composed of cast copper and therefore has the strength only of cast copper but its tenacity may be increased by hammering where permissible. If the joint is to be hammered after welding it should, of course, be made somewhat thicker than otherwise would be required in order to provide sufficient metal for hammering flush with the remainder of the sheet.

Brass and Bronze

Brass is an alloy chiefly of copper and zinc while bronze is composed principally of copper and tin. There are many of these brass and bronze alloys containing variable proportions of the principal metals and percentages of other metals such as lead, antimony, etc. No rigid rule can be laid down for welding them except that the welder must exercise caution to avoid overheating and burning out the metals of low melting temperature. It is especially important to avoid overheating brass, as the zinc content burns out at a comparatively low heat. The burning of zinc in brass is betrayed by dense white fumes which are poisonous. Breathing them should be avoided.

Adjust the flame with the cone the same as when welding aluminum and keep the point of the cone away from the metal to distribute the heat more than when welding steel. Form a puddle of molten metal and add Marvel welding rod to the puddle, using flux to prevent oxidation. It will be necessary on account of the radiating capacity of these metals to use a larger tip than required for an equal thickness of steel, the same as when welding copper.

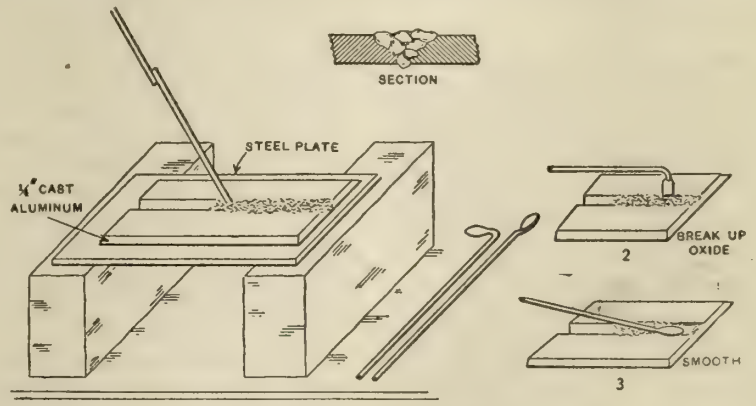
When white fumes rise from the joint the welder should reduce the heat as this is an indication that zinc is being volatilized and the joint metal weakened.

The welder should study every job and if in some cases it appears that the parts can be brazed satisfactorily he should have no hesitation in brazing in preference to welding. Brazed joints can be made with less heat than required for welding. On thick metal it may not be feasible to braze in which case the job must be beveled and treated the same as steel or cast iron.

Preheating large brass and bronze sections is desirable and often necessary to prevent serious internal stresses that might cause cracks or failure in service. Preheating also reduces the amount of gas required for the actual welding and while cooling off.

Naval Bronze

Certain bronzes, including the so-called Naval bronze can hardly be welded with the oxy-acetylene torch by the average operator without producing numerous blowholes in the point. Blowholes are not permissible, of course, where strength and tightness of joint are required. The trouble can be overcome by reducing the heat, holding the flame further away than when welding iron, and using steel puddling hook or spoon to work out the oxide, the same as when welding aluminum. Briefly, these difficult bronzes may be welded at a temperature but little above the fusion point and by mechanical manipulation which works the metal into the joint and removes the oxides produced.



Welds can be made in bronzes by the puddling process free of oxide and blowholes that offer tensile resistance up to 90 per cent or more of the full strength of the unwelded section. In fact, experts have been able to produce nearly 100 per cent. strength joints in this manner.

Galvanized Sheet Steel

Welding of galvanized sheets is not in general advisable. The heat necessary to fuse the metal burns the zinc and the resulting weld is affected by the absorbed metal. Moreover, the protective coating is destroyed and the welded joint will be subject to corrosion. Soldering with a lead-tin mixture is recommended for containers under light pressure and hard soldering for seams required to withstand considerable stress. A brazed joint is very strong; brazing amalgamates with the zinc and forms a union which resists corrosion well.

Nickel

Nickel conducts heat rapidly and requires a larger tip for welding than steel at the same gauge. It should be treated about the same as copper in this respect; use nickel filling rod. Having attraction for oxygen when fused it is desirable to employ a slightly carbonizing flame when welding nickel and alloys high in nickel content. The strength of nickel drops off greatly at certain temperatures considerably above normal, there being two well defined critical points in the temperature range at which the metal is quite brittle. These critical points are about 850 and 1,750 degrees F. Under some conditions the welded seam will crack, especially if under strain as it cools down. This trouble may be averted by reducing contraction stresses to a minimum. When the metal is cold the seam is still likely to be brittle until mechanically worked in compression. Then it may be heated and annealed. A welded joint should not be annealed before being worked mechanically as it is quite likely to crack in the process. But when the physical characteristics of rolled metal are imparted to a weld by mechanical treatment a welded sheet may then be safely subjected to annealing, drawing, rolling or other process required in fabrication.

Welding aluminum sheets.

Monel Metal

Monel metal is a natural alloy of nickel and copper having a silvery appearance similar to nickel and polished steel. It is very strong and highly resistant to most acids and alkalis. Because of its resistant properties and high tensile strength especially when hot it is be-

ing used more and more in chemical apparatus, steam turbines and other machinery. Monel is readily welded with the oxy-acetylene torch using a slightly reducing or carbonizing flame. The method of welding is the same as employed for other metals, the joint being beveled and monel welding rod used for filler.

The nickel in monel has a strong attraction for oxygen and in some cases it may be advisable to use Marvel flux to reduce the oxidation and to eliminate the oxide formed. Preheating of monel should be done only with charcoal or other fuel free from sulphur as this element is freely absorbed by the metal when hot with consequent injury. If oil burners are used the oil should be as free from sulphur as can be obtained. Acetylene must also be free from sulphur, and the best results will be secured with acetylene purchased compressed in cylinders which when furnished by the leading manufacturers is carefully purified to eliminate sulphuretted hydrogen and other injurious gases. If generated acetylene be used special provision should be made to purify the gas. Some grades of monel wire contain considerable iron and these should be avoided as the best results are obtained with monel welding rods free from iron and sulphur.

Welding Monel Sheets

Thin monel sheets requiring splicing may be welded by clamping together between two steel bars, allowing about ⅛ inch to project for welding. The edges are fused with the flame, generally without using flux or adding material. The No. 0 or No. 1 tip will generally serve the purpose.

When welding has been finished the sheets are opened like the leaves of a book and pressed down on a flat surface, hammering on top of the weld with a wooden mallet or block to bend the sheets to right angles with the weld flange. Usually the flange or weld is allowed to project at right angles to the sheet.

The same procedure may be followed of course when welding any thin sheet metal or metal cloth, especially when no bending brake is available for turning flanges.

Manganese Steel

Steel containing certain percentages of manganese and heat-treated is very tough and wear-resisting. It is used for railway frogs, crossings, guard rails, for dredger bucket lips and for other purposes where the ordinary grades of steel would be quickly worn out. Manganese steel castings may be welded with the oxy-acetylene torch using special managanese steel welding rods. No flux is required as the manganese content acts as a deoxidizer.

Preheating is necessary to secure the best results and care must be taken to secure thorough penetration. Inasmuch as manganese steel cannot be cut with ordinary cutting tools beveling must be accomplished by grinding or with the cutting torch. Manganese steel should be heat-treated after welding to restore toughness. Quenching when hot softens and toughens the metal instead of hardening it as with carbon steels.

Welding Dissimilar Metals

Dissimilar metals such as cast iron and steel, etc., may be welded successfully. A rule to be observed in the welding of dissimilar metals is to concentrate the flame on the metal of the higher fusing temperature and to use adding material of the same physical and chemical characteristics, corresponding to the metal of the lower melting temperature. For example, when welding cast iron and steel, use cast iron adding material.

Cast Iron to Steel

To weld cast iron to steel use Atlas cast iron welding sticks and Atlas scaling powder. The steel must be fused first because the cast iron melts at a lower temperature. The manipulation of the torch should be such that the heat is mostly distributed to the steel which requires the higher temperature for fusing. Comparatively little scaling powder is needed.

Copper to Steel

Fuse the steel and bring the copper into contact and let the heat of the steel melt the copper and blend with it. Use little Marvel flux. It is not feasible to weld long copper and steel joints except in spots because of the difference in expansion and contraction of the two metals, but it is sound practice to weld copper bonds to steel rails as a perfect and enduring electrical joint can thus be made quickly. Reinforcement, if desired, may be made by using Anaconda copper rod but in all cases the heat of the steel must fuse the copper as otherwise a perfect joint will not be obtained.

High-Speed Steel to Machinery Steel

High-speed steel bit may be welded to machinery steel shanks with the torch and thereby produce large lathe and planer tools at low cast as compared to the cost of making the whole tool of high-speed steel. The procedure recommended is "tinning" the high-speed steel bit with D-B special welding rod applying welding rod until sufficient adding material has been deposited to permit the piece to be welded to the machinery steel shank in the usual manner.

Another method of welding high carbon and high-speed steel to low carbon steel shanks is successfully employed for lengthening drill shanks, known as compression welding. To carry out this work a special holder or jig is required to hold the drill and shank in line while being heated with the torch flame. When both are heated to the fusing temperature the drill is struck with a wooden mallet and driven against the shank thus producing a compression weld. The resulting flash collar is ground off.

Welding Dissimilar Metals

Almost any combination of dissimilar metals can be welded without serious difficulty by timing the part of higher fusing temperature with adding material of lower melting point that is suitable for welding the metal of the lower fusing heat. When sufficient adding material has been deposited and fused to the part the two pieces are then ready for welding in the usual manner. Care must be taken when starting to weld to direct the flame upon the metal and adding material of the lower fusing temperature only. Consider the tinned part as finished; any attempt to reinforce this part of the weld is likely to result in failure of the job.

Nickel to Iron and Steel

Nickel may be welded to mild steel readily the same as another piece of steel. Requiring a somewhat higher temperature than steel, the flame may be directed against the nickel more than the steel. Steel adding material should be used. The attempt to weld long seams in nickel and steel should not be made though without special precaution on account of the difference in expansion. The expansion coefficient of nickel is about 20 per cent. higher than that of steel. Nickel is used successfully for filling in scratches and score marks in cast iron gas engine cylinders, uniting readily with the iron and making a dependable wearing surface.

Welding Smokestacks

Steel smokestacks corrode in the seams and require replacement every few years. The combination of rain and snow on the outside and the hot gases inside works havoc on riveted joints. A welded smokestack lasts much longer than the riveted stack and is much stronger in resisting wind stresses. There being no crevices nor rivets in which moisture may collect or products of combustion lodge, there are no points at which corrosion is likely to be more acute than at others. The wasting away of the stack by the elements and the gases, therefore, must proceed fairly uniformly throughout and the stack will remain in serviceable condition for a long time. A welded stack is like the famous one-horse shay; when it fails, it goes to pieces all over.

Wire Cloth

Woven wire screens used in chemical plants and by other industries may be repaired with the torch to great advantage. Often a hole will appear in a screen when the remainder is still in good condition. The hole can be filled in a few moments, and the life extended several weeks or months. Of course, the welded portion will no longer act as a screen but usually this will not matter.

Bending with Aid of Torch

Repair men using welding torches soon learn to apply them when bending and straightening shafts, bars and structural parts. A workman who understands heating in just the right spots can quickly straighten a badly bent piece with the expenditure of very little gas and manual exertion.

(To be Continued)

(Continued from page 20)

INCREASING MAN POWER

will find myself." There is something delightfully strange about this thing of helping others, for in some mysterious way we always help ourselves. This law is as old as Human History, yet as young as Modern Business, for it is the real foundation of all successful industries to-day.

Set a Good Example

You must at all times remember that your men have a right to follow the example you set. It is impossible for a leader to disregard a proper observance of the rules he asks his subordinates to follow. It must be embarrassing indeed, for one to reprimand a man for breaking a rule that he himself breaks.

Setting an example implies a proper dignity. People expect to see in their leaders a dignity befitting their particular stations. I do not mean snobbish aloofness, nor a superior attitude: A leader should never be forbidding nor haughty, neither should he be "One of the boys" in the old sense of the phrase. He can be decidedly friendly and approachable, without being too chummy. Character has a dignity of its own, and it would be hard to imagine a man utterly devoid of character who could have any dignity whatever, except such as might be supplied by clothes and appearance. Dignity and character go hand in hand, in giving to a leader the marks that stamp him and instill in his followers the respect and admiration so essential to a continuance of that relation.

In this connection I wish to speak of the matter of personal appearance. By this I do not mean that foremen and executives should wear good clothes or dress up to any standard, but I do mean that no leader who has any respect for himself can expect any respect from his subordinates if he persists in slovenly appearance. You don't have to wear new clothes to be neat and clean. It is far better to have on a clean suit of faded overalls, a clean shirt and clean shave, than an old suit, dirty and shabby, and several days of beard glistening in the sun. A satisfactory personal appearance can be maintained without spending much except time and care. While clothes do not make the man, still the way in which he wears them proclaims a good deal about his habits.

Maintain Discipline

In walking through the plant, I sometime observe men who are either loafing or not applying themselves properly. If they chance to see me they usually hustle around and try in various ways to make it appear they are very busy. In fact I have seen whole departments take on an air of increased activity as soon as my presence was known even though the foreman had been there all the time. The foreman of such a department certainly is not maintaining the right kind of discipline. His discipline is all a farce and to be used only in cases of dress parade or inspection.

Discipline that results in effective work cannot be maintained by rules and regulations alone. There is required a sort of mutual interest on the part of the foreman and his men that only real leadership can secure.

I do not believe most people attach as much importance to this factor as they should. In my opinion it might well stand at the head of the list because it so closely touches and influences the other factors. The whole structure of human relations rests so firmly on confidence that you cannot get far if you disregard the influence of your personal character. Character is not something of clothes; it is not acquired over night; it takes time to build it and we never quite finish the task. Watch out for the little slips that cause deficiencies, for these may result in a streak—a yellow streak.

You may think it amounts to little, but some day you are called upon perhaps to stand out for inspection and the streak is noticeable. Then you fall short of a complete influence. Men will have confidence in you if you have built up a reputation for fairness, justice, sympathy, integrity and all the other virtues that go to build character. Clean living, clean thinking and clean speech with a whole hearted and active effort to acquire those characteristics and human traits that you admire in other leaders will develop in you the character so necessary to all those who aspire to be Managers of Men.

MACHINE WEAR AFFECTS QUALITY OF PRODUCTS

(Continued from page 23)

destruction of the necessary accuracy Of late years forced lubrication has had to be practised more and more, especially for those types of bearings subject to continued pressure in one direction, or for slides which are covered for good portions of the cutting time, and hence do not gain an opportunity of relief and access of fresh lubricant by long traverses over the rest of the ways. Ample grooving supplies the means of ensuring the presence of plenty of cool oil in these cases, and the pressure system guarantees a continuous flow irrespective of the mechanical action of the rubbing surfaces in producing distribution—an uncertain and variable matter. Some kinds of bearings require the oil to be delivered at the spot or line of greatest pressure, which may be at the top in some classes, at the bottom in others. Freedom of running, and regularity of wear are consequently made sure of according to the special needs of each bearing; even on the same type of machine, such as a lathe, for example, the pressure may be quite different, if one lathe is employed chiefly on a distinctive class of cutting from another. The utilisation of double tools, set opposite, also alters the state of affairs, so also may simultaneous operations, as turning and boring, or boring and facing, etc.

DESIGNING THE SCREW THREADS

(Continued from Page 25)

mechanics contains the derivation of the above formula for the inclined plane.

In the case of the V-thread, the normal pressure on the nut is greater than with the square thread according to a ratio that depends on the cosine of half the angle of the thread. So that for a 60 degree thread we have the efficiency equals.

$$\frac{\tan \alpha}{\tan (\alpha + 1.14\,\phi)} \quad (42)$$

In many cases, in addition to the thread friction, there is a collar thrust friction which may have to be considered. If the thrust collar is the same diameter as the screw thread then the combined efficiency is

$$\frac{\tan \alpha}{\tan (\alpha + 2\phi)}$$

Any extra friction would be treated in the same way.

The expression

$$\phi \quad \phi \quad \tan (\alpha + \phi)$$

may be written in another form because of a trigonometric relationship, thus

$$\tan(\alpha + \phi) = \frac{\tan \alpha + \tan \phi}{1 - \tan \alpha \tan \phi}$$

Very often this expression admits of direct substitution to give the required result.

Example:—A square threaded screw 2 inches in mean diameter has two threads per inch of length. The coefficient of friction between the screw and the nut is .02. Determine the horizontal force applied at the circumference of the screw that will be required to lift a weight of 3 tons. Find the efficiency of the screw. The pitch equals ½ equals P, mean dia. equals d, equals 2"; Tangent of angle of inclination of the thread.

$$\tan \alpha = \frac{p}{\pi d} = \frac{.5}{3.14 \times 2} = .0794$$

$$\mu = .02 \text{ so that } \tan \phi = .02$$

Let Q equal the force in tons necessary to do what is required. Q equals the force applied at the mean radius of the thread to lift the weight

$$= W \tan (\alpha + \phi) \quad \text{or}$$

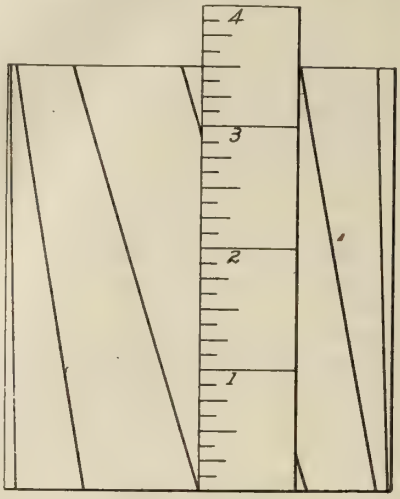
$$Q = 3 \times \tan (\alpha + \phi)$$

$$\text{or } Q = 3 \times \frac{\tan \alpha + \tan \alpha}{1 - \tan \alpha \tan \phi}$$

$$\text{equals } 3 \times \frac{.0794 + .02}{1. - .0794 \times .02} \text{ equals } 3 \times .09956$$

equals .2987 tons.

Also the efficiency equals.



$$\frac{\tan \alpha}{\tan (\alpha + \phi)}$$

Practical Ideas for Shop Executives

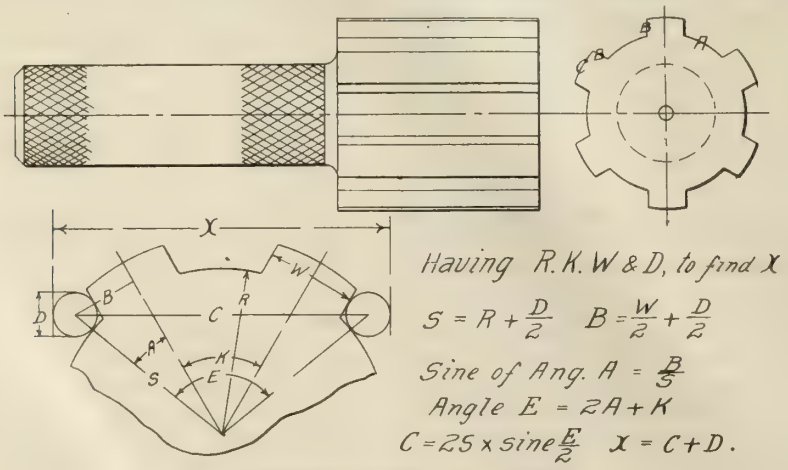
A LITTLE knowledge is often a dangerous thing." This is particularly true respecting the lubrication of machinery. Many men think efficient lubrication means "plenty of oil." But the proper definition should be "enough for the particular purpose." This applies both to quality and quantity.

One place where the use of oil is often abused is on the feed screws of machines, particularly lathes and shapers. It is, of course, necessary to lubricate these units but not profusely, as too much oil causes the dust and cuttings to adhere to the thread and when drawn into the nut, results in excessive wear. Especially is this true in the case of cross feed screws on lathes where no cover is provided and cuttings revolve with and adhere to the thread as the tool is advanced or withdrawn from the work. Wherever possible these screws should be protected from the falling dirt and cuttings. Where parts, such as gears, worms, thrust bearings, etc., are completely enclosed, a generous supply of oil is often advisable, but in no instance should more oil be used than will adequately answer the purpose.

Undue waste of oil often occurs in the lubrication of counter shaft and main shaft bearings, and this duty should always be under the supervision of a man with a full knowledge of the requirements and the most suitable oil for the purpose. I have in mind a large industrial plant where an old man had this work to do and more oil was wasted each trip than that placed in the bearings. He would climb the ladder and invert the oil can before he located the oil hole, with the result that more oil found its resting place on the outside of the bearing box than that going into the oil well. His trail could usually be traced by a small pool of oil on the floor beneath each bearing. Proper care on the part of the executives and the man in charge of this work would result in a profitable saving of oil.

Lead of spiral cutter.

LEAD OF SPIRAL CUTTER



By J. Davies

In answer to the tool room problem in Feb. 16 issue: "How to find the lead of a spiral milling cutter from the cutter itself," I submit the following. Place the cutter on the marking-off table or surface plate and apply an ordinary scale as shown in the sketch. Place the scale at end of one tooth and note the distance where the edge of the scale cuts the line of the next tooth. Multiply this distance by the number of teeth and it will be very close to the lead. The sketch shows a lead of 30 in., 3 inches for one tooth with a ten tooth spiral.

MALE SPLINE GAUGES

By Geo. R. Brooks

The accompanying cut illustrates the method adopted in grinding and gauging male spline gauges for inspecting splined holes in automobile differential slide gears. As it is very difficult to make an indexing fixture that will be accurate to .0002 of an inch, the splines must be ground another way. The ordinary index centres for the surface grinder can be used with two screws opposite each other for clamping the tail of the dog, instead of the usual method of one screw. This allows of closer adjustment. The centres are then checked for alignment. The first operation is to grind the bottom A of the spline, to correct diameter and concentricity. The second operation is to grind two opposite sides B central, and correct thickness. The accompanying formula is used to determine the location of the other splines. Extreme care must be exercised in making the splines the exact thickness, or the last spline ground will be unequally spaced. The gauge is then finished by grinding the outside diameter C to size. A careful gauge maker can grind this gauge to an accuracy of .0002 of an inch.

Grinding and sizing spline gauges.

ELECTROPLATING AND MACHINE REPAIRS

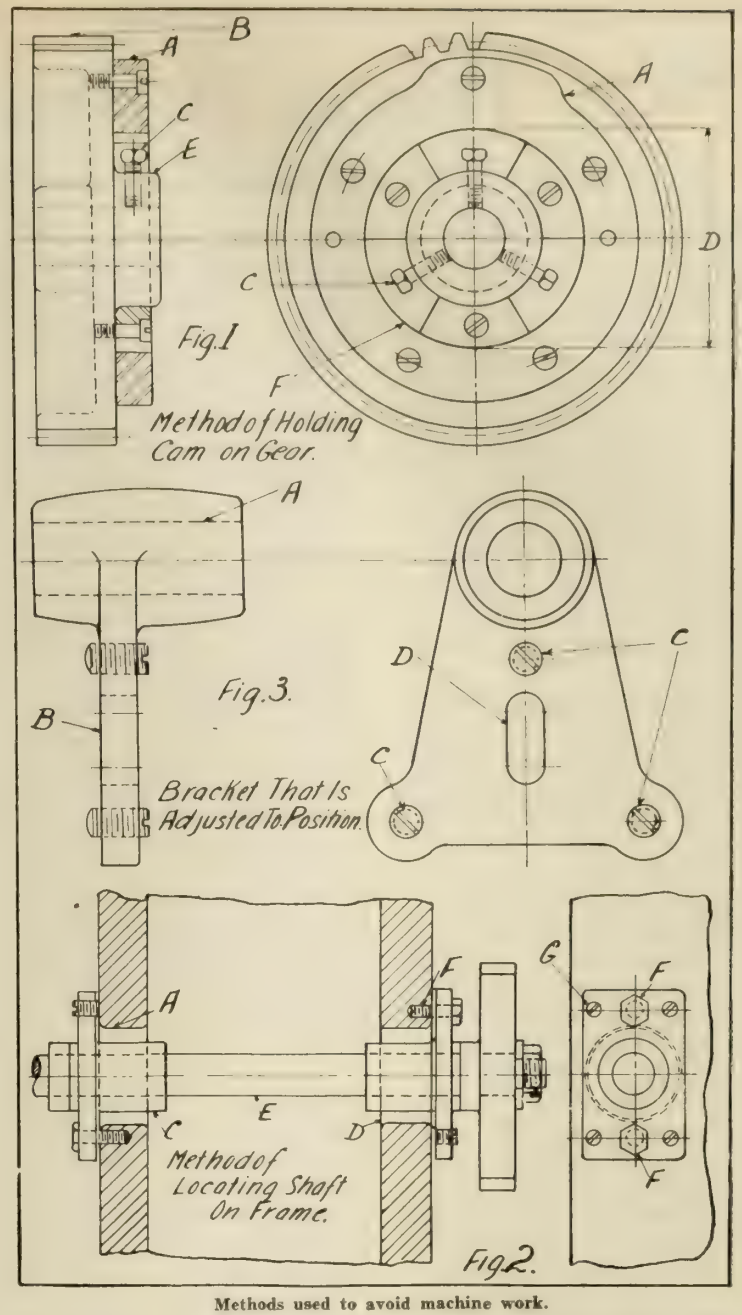
The loss of even a small fraction of an ounce of metal from some part by wear often makes it necessary to purchase a complete new part or, if this be unobtainable, to lay up the whole machine as an alternative to working it under very unsatisfactory conditions. In many cases, however, worn parts can be restored to their original dimensions by depositing on them electrically a film of metal—nickel is good on account of its hardness—of the requisite thickness, wtih a little to spare if subsequent turning or grinding be necessary. The part is thoroughly cleaned and dipped into melted wax. When the film of wax has cooled, says a writer in the British Trade Review, it is scraped away from the surfaces which require treatment, and part immersed in the plating bath. As the metal is deposited very slowly it is easy to work to very close limits; yet, if sufficient time be allowed, the deposit may attain a thickness of 1/10 in. or more.

If the operation be properly carried out, the nickel adheres to its foundation very tenaciously, and is quite continuous and of even thickness throughout. In this way expensive and heavy items, such as crankshafts, cylinders, and pistons, can be made serviceable again at a cost far smaller than that of a new part. At the other end of the scale very slight wear in delicate machinery, in which close adjustment is essential, may be put right by the deposition of a film of the exact thickness required.

MACHINE UNIT ATTACHMENT METHODS USED TO AVOID MACHINE WORK

By F. H. MAYOH

TWO CLASSES of work which give a good deal of trouble and often run up a costly manufacturing bill, are attachments which have to be put on machines already in use, and special work too large to be handled on the tools that are available to do the machine work. The reason for this is usually obvious because of the large amount of hand work necessitated thereby. The group of illustrations shown herewith are of designs used to obviate to some extent manufacturing trouble under such conditions.



Securing Cam to Gear

Figure 1, shows a cam that was attached to the side of a gear, the cam being indicated as "A" and the gear as "B;" to attach the gear on the shaft upon which it was mounted three set screws "C" were employed. As it was desired to avoid the expense of removing these screws and using some other means of attaching the gear to the shaft, a hole was bored in the cam of a diameter equal to "D." A ring was also made having an outside diameter to fit this inside diameter "D" and a hole to fit the hub of the gear at "E." This ring was cut into six sections and three of the pieces "F" were interposed between the gear hub and cam while screws held them in place, thereby centralizing the cam on the gear. The cam is held in position by screws and dowels and as there were two of these gears with cams attached all of the six pieces "F" cut from one ring were used. The saving in this instance consists of having to do no machine work on the gear and the arrangement as shown permitted of revolving the cam on the pieces "F" until the rise of the cam was in the proper location, in time with the other operating units of the machine.

Adjustable Bearing

Figure 2 shows a method sometimes used to locate a shaft in the base of a machine where the base is too large to go on any of the boring machines available or it might be used to attach a shaft to a machine already set up and upon which additional mechanism is to be assembled. In this instance the two large holes "A" and "B" are cast in the machine or cut out by using hand equipment depending, of course, on the circumstances. These openings are made large enough to permit of adjusting the bearings "C" and "D" which carry the shaft "E" until both ends of the shaft are in line and the center distance correctly located with reference to the other parts of the machine. After this the screw holes are drilled and tapped as indicated at "F" for the purpose of holding the bearings in place, each of the bearings having a large flange cast integral therewith for this purpose.

As shown in this example two holding screws "F" are employed and in each of the four corners of bearing at "G" are placed headless adjusting screws. These are adjusted to line the bearing up on the rough surpace of the casting and after the shaft runs properly, in the correct location, tightening screws "F" securely holds the bearing in place. The bearings can then be doweled in position, or if desired babbitt, or lead may be poured between the bearing flange and the machine thus holding the bearing securely in place and preventing them from getting out of alignment when in use.

Methods used to avoid machine work.

End Support For Shaft

A form of bracket used in somewhat the same manner is shown by Fig. 3 except that this bracket is part of the regular construction of a commercial machine. It is used to support the end of a shaft that has two fixed bearings in the machine proper. The shaft end overhangs considerable and this bracket is slipped over the shaft at "A," the surface "B" is then pushed up against the rough side of the machine and the three screws "C" are adjusted until th come in contact with the side of the machine and permit the shaft to revolve properly. A screw passing through the slot "D" then clamps the brackets securely in position for the purpose of supporting the shaft.

The principle involved in the last two illustrations will be found quite a convenience in building first models where the factory is not properly equipped to manufacture, and in fact on some types of machines most of the heavy machine work can be eliminated in some such manner if it is not convenient to do the same, although it will be understood that these methods are somewhat of a makeshift and should not be employed in good high class commercial machine construction where important functions are to be performed.

New Things in Shop Equipment

PORTABLE ELECTRIC DRILL

A portable electric drill has recently been placed on the market under the trade name of "Willey." It is made in three sizes, 3/16-inch, ¼-inch, and 5/16-inch, these sizes weighing 6½, 7 and 7¾ pounds respectively. The drill is constructed in three units, namely: a motor body, drill spindle, gears, and the handle. The handle is provided with a mechanism for controlling the motor switch. This mechanism is actuated by the fingers of the operator in grasping the handle. Thus the drill automatically stops rotating when the pressure of the hand is released from the switch mechanism. All electrical connections and attachments are contained in the motor body.

The tool is designed for use with high speed drills only when drilling in steel or iron. It is intended that carbon steel drills be used for the softer metals and wood. The drill is manufactured by the James Clark, Jr., Electric Co., Inc. of Louisville, Ky.

OIL CUP FOR LOOSE PULLEYS

An oil cup has recently been designed to efficiently and economically lubricate loose pulleys. It is claimed that the oil cup will keep the pulley shaft well oiled while the pulley is revolving and at the same time does not allow oil to empty from the cup and leak along the shaft when the pulley is stationary and the oil cup is above the shaft centre. The method of mounting is rather simple. An oil hole is drilled through the hub of the loose pulley, to the bore. The outer end of the hole is tapped to receive a special cast iron elbow. One end of this elbow is slightly longer than the other. The long end is used to carry the oil cup away from, and clear of, the hub. The oil cup is screwed into the elbow. It is of simply a reservoir design with a neck on the end. The central line through the oil chamber is set at 45 degrees to the central line through the neck connection. When screwed in place the reservoir should incline toward the pulley hub. The only unusual part of the construction is a small round rod in the neck connection. This rod acts as a valve and keeps the passage way unobstructed, the pin or rod only moving when the pulley is stopped or started. This rod or pin serves to regulate the flow of oil. The top of the reservoir unscrews to permit of filling with oil. The oil cup is manufactured by Charles Kay of 5,073 Burns Ave., Detroit, Mich.

NEW TYPE OF REAMER

A new type of reamer having three right hand spiral flutes, rugged cutting lands, and milled with a generous hook or undercut has been recently placed on the market and for which some unusual results are claimed. The taper pin type of reamer is sharpened so that two of the lands are relieved clear up to the cutting edge, while the third land is only relieved for about two-thirds of its width, leaving the balance of a circular section to act as a steady rest and prevent the right hand spiral and undercut from drawing the tool into the work. Contrary to usual experience, this type of taper reamer gives best results when operated by power. When cutting steel, the cuttings resemble a bunch of steel wool. The taper reamer it is claimed, will not draw into the work, cannot chatter, cuts like a drill and works best when power driven.

The same idea of design has been applied successfully to a chucking or hand reamer for straight or parallel holes. In this case the reamer is made with three equally spaced and fully relieved cutting lands, while midway between two of these is a narrow unrelieved land which acts as a steady rest to keep the reamer from drawing in or chattering. It also serves, in connection with one of the cutting edges, to furnish a place to measure the diameter of the reamer. These reamers are manufactured by the Bickford-Switzer Co., of Greenfield, Mass.

AUTOMATIC DRILLING MACHINE

There has recently been placed on the market an automatic horizontal multiple spindle drilling machine of the station type. This drill press has two horizontal heads, each of which contains a multiple number of drilling spindles. The machine has been tried out on a varied class of work in light drilling. A piece of work in a jig is placed on the work-holding fixture in the middle of the bed. The two heads are fed toward, and away from, the jig at the same time, the operation of the machine in this respect being automatic and continuous. The duty of the operator is to change the work at the front station of the work-holding fixture and index this fixture through the stationary jig. An indexing occurs each time the drill heads are withdrawn from the jig.

The drill spindles are provided with radial and thrust ball bearings and all spindles are run at the correct speeds for the diameters of drills they are driving. The feed of drills is reduced as they enter and break through the work. Quick returns are provided for the heads. Various heads can be used on the slides, very little time being consumed in changing. The saddle, or work-holding fixture, is so designed that a wide range of work can be accommodated. The machine is about ten feet long and weighs approximately 5,000 pounds.

PNEUMATIC RIVETING MACHINES

A line of pneumatic riveting machines, made in various capacities from 10 to 150 tons, is now being built. Movement is given the die, in these machines, through a toggle action which causes the die to advance to the rivet rapidly at first, but at a decreasing rate of speed and an increasing tonnage. After the die reaches the rivet, uniform speed and pressure, sufficient to drive the rivet tight, is provided, thus drawing the plates together, and following up the shrinkage of the rivet with full pressure. It is not desirable, nor is it necessary, to drive the rivet at the end of the die travel or piston stroke. Thus it has been intended that when the die is set for any run of work, that the rivet will be headed when the piston has moved through about three quarters of its stroke. This leaves a sufficient die travel at full pressure on either side of this position to take care of variations in the length of rivets, thickness of plates, dimensions of holes, etc., without it being necessary to make further adjustments of the die screw. The first inch of piston stroke results in a die travel of 1¾ in. Four-sevenths of the power is developed at the die during the movement. Thus a five-ton pressure exerted by the piston results in only 2.85 tons pressure being exerted on the die. In the second inch of piston stroke, the rivet die advances 7/16 in., exerting a pressure of 11.4 tons. The third inch of piston stroke advances the rivet die 5/16 in., with a die pressure of about 16 tons. For the ninth and each succeeding inch of piston stroke the die advances 1/12 in. and exerts a pressure of 60 tons on the rivet die, this maximum pressure being maintained for ½ in. of die travel.

The operating valve is of the plain sliding type having a simple wick packing on the stem, and a removable valve seat which permits of easy regrinding. The machine is provided with means for using line pressure in the pull-back area. This reduces the pressure to the next lower tonnage rating which enables a 50-ton machine to develop and operate at both 50 tons and 30 tons pressure on the rivet die. Similiarly a 75-ton machine will operate at both 75 tons and 50 tons die pressure. The machine is manufactured by the Southwark Foundry and Machine Co., of Philadelphia, Pa.

ALIGNMENT GAUGE

As perfect alignment of connecting rods is essential if an internal combustion motor is to give the best results, and be free from many common troubles, the introduction of the "Twistest" connecting rod gauge will be welcomed by manufacturers of motors. The gauge consists essentially of a cast iron base and on one side flush with the edge, is located a vertical plate integral with the base. On top of the plate, and cast integral with it, are three vertical standards well tied together with cast integral ribs. In the solid vertical plate is located a ground hole surrounded by a circular machine finished facing piece. In this hole is inserted the steel pin used as a gauging part and which lines up the large end of the connecting rod in a manner precisely as it is assembled on a crank shaft. In the small end of the connecting rod a steel pin is placed and attached to this pin is a four pointed star of cast iron. On each corner of the star is a machine finished pad ground true. The rod is placed on the large pin and the small pin is placed in the rod. The four points on the star are widely separated and should touch the three vertically machine ground ways of the gauge. The middle way has two star points in contact for alignment in the one plane. The two other star points should come in contact with the two outside ways to test the alignment in the other plane at right angles to the first plane of reference. If all four star points touch, the rod is in alignment. Feelers are not required as the construction of the gauge enables the contacts to be verified by the eye through the light test. A complete range of large pins for the crank shaft end of the rod and stars on small pins for the wrist pin ends is manufactured. The size of the star is sufficiently great to magnify the error to a great extent. The capacity of the gauge is for rods from 6 inch centres to 12½ inch centres. The gauge is manufactured by J. S. Imlach, Ottawa, Ontario.

DIAL FEED MULTIPLE SPINDLE TAPPING MACHINE

An electric driven three spindle dial feed tapping machine has recently been placed on the market. The work holding dial is indexed by means of cams mounted on the main vertical spindle. The machine was designed primarily for tapping nuts and other small pieces requiring a number of tapped holes. Such parts in brass and steel are required in large quantities in electrical apparatus. Any piece requiring one, two or three tapped holes can be tapped at one movement of the dial past the spindles. Taps of different leads can be used on the several spindles at the same time. The two outside spindles are adjustable so that holes in varied and staggered positions may be tapped. One hole is made to register with the centre spindle and the outside spindles adjusted to the other holes in the work. Taps from size No. 4 to No. 10 are operated at a rate of 56 strokes per minute, which gives an hourly production of 3360 pieces having either one, two or three holes. On pieces with only one hole to be tapped, production can be increased by 100% by doubling the number of slots in the dial, which can be conveniently done by staggering them and adjusting one of the outside spindles to suit. This gives a production of 112 pieces a minute. By furnishing a cam and a slide which will work in conjunction with the dial the machine may be modified so that round pieces may be tapped without difficulty. Ball bearings are provided for all shafts that run at comparatively high speeds, and all gears are accurately cut. The motor is mounted on a bracket attached to the column and it is directly connected. The machine is manufactured by the Anderson Die Machine Co. of Bridgeport, Conn.

LARGE ROLL GRINDING MACHINE

Recently there were built two large roll grinding machines which are capable of grinding rolls up to 54 in. in diameter and 28 feet in length. These are believed to be the largest machines of their kind ever built, the weight being about 50 tons, for each machine. Electric drive and control throughout, has been employed. The drive for each machine comprises four motors. A 40 h. p. motor on the wheel carriage operates the grinding wheel and traverses the carriage. A 20 h. p. motor on the head stock revolves the work. A 3 h. p. motor on the foot stock traverses this member along the ways of the work base. A 3 h. p. motor on the wheel carriage drives the coolant pump and traverses the grinding wheel at right angles to the work.

The operation of the machine is governed by magnetic controllers, the position of the operator being on the wheel carriage beside the wheel where the grinding process may be observed. Rolls may be rotated between centres or on bearings. When the operator is in his position there are within reach all the handwheels and levers necessary for stopping or starting the roll, reversing the traversing wheel carriage, either by hand or by power, starting and stopping the traverse of the wheel carriage changing from the maximum to the minimum speed of the wheel carriage traverse, moving the wheel carriage for slight adjustments by hand, moving the wheel toward or away from the work either by hand or by power, and controlling the amount of coolant water flowing over the work.

Changes in the speed of the work are accomplished at the head stock by means of a drum controller and change gears. Four speed changes for the traverse of the wheel carriage are accomplished by means of a lever on the front of the carriage. Eight speed changes for this unit are available through the use of back gears. An attachment adjustable to any radius up to 3½ inches is furnished for forming the corner of the grinding wheel to suit the grinding of fillets while the trueing device maintains the face of the wheel. The machines were designed for dressing steel mill rolls and were recently installed in the shops of the Jones and Laughlin Steel Co. The manufacturers were the Norton Co., Worcester, Mass.

FORM AND CUT OFF MACHINE

An automatic machine with two spindles designed to have two operations only, form and cut-off, has recently been developed and placed on the market. The two spindles work simultaneously as two separate single spindle machines working on different pieces of the same product. The machine will make any one piece that can be produced with one forming and one cutting-off tool, or with a forming tool and a combined forming and cutting off tool. Under these limitations come the pieces such as special shaped rivets, knobs, studs, handles, etc., etc.

The two spindles are placed side by side and the double set of forming and cutting-off tools work together on two bars of stock, producing two pieces in the time required for one. Adjustments are provided in all directions which greatly facilitates setting up. All adjusting members are graduated. The machine is rigidly designed enabling heavy cuts at high speeds to be made without vibration. All parts are amply proportioned for heavy duty service and long life, yet simplicity is evident. The spindles are hardened ground and lapped, and operated in phosphor bronze boxes of adjustable design. Thrust is taken care of at the rear end of each spindle through the medium of hardened steel and phosphor bronze bushings. The spindles are driven from a three step cone pulley shaft, through enclosed spiral gearings running in oil. The pulley shaft runs on roller bearings. Six chucks are easily changed and are adjusted by a nut at the rear end of each spindle. There is no end-motion when opening or closing the chucks.

Work can be fed in any length up to three inches but by means of a special arrangement lengths up to twelve inches can be fed. Feeding may be accomplished at any time during the revolution of the cam shaft. The forming tools are carried on cross slides and can be adjusted independently in any direction. The cutting-off slides are set at an angle to provide extra clearance for the forming tools. Tools can be adjusted independently or in unison. Change gears supplied with the machine permit of a production of from 60 to 1,800 pieces per hour, the rate depending upon the character and size of the part. The floor space required is 44 by 26 inches. The manufacturers are the L. P. Brown Machine & Tool Co. of Attleboro, Mass.

The report is current that the Wabash Railway Co., is planning the erection of a locomotive repair shop at St. Thomas, Ont. in the near future, at a cost of about $500,000, in order to take care of the rapidly increasing business in Canada.

Standardization is Needed

IN THREE months' time, the mechanical engineers of Canada and the States will open up a convention at Atlanta, Ga. One of the chief topics to be considered will be standardization of industry, and it is to be hoped that important rulings will be passed on that occasion as there is a great need of standardization in all industries at the present time.

Germany has found the benefit of standardizing their products, and a few pioneers of the movement in this country have made a success, in a mild way at least, towards producing standard lines. They usually classify this as simplification of their lines, and by reducing the number of styles carried, made a forward step towards standardization. This, however is only local in character, and what we urgently need is a nation-wide movement.

Standardization, if properly applied, stabilizes production and employment. It allows manufacturers to plan accurate stocks during slack periods, and reduces automatically the selling cost. It also lowers the unit cost to the buying public by making mass production possible. The automotive industry is an ideal example of standardization. Another feature is that by concentrating on fewer lines, a manufacturer can place more thought and energy on the products being manufactured.

Before the war, pocket knife manufacturers in the States made as high as 650 basic patterns for pocket knives, and from the 650 patterns, as high as 6,000 to 7,000 distinct numbers or styles were evolved. Under government regulations this enormous amount was reduced to 85 basic patterns, and 250 knife styles, and speaking of the change, C. W. Silcox, secretary of the industry said that they found that they had formerly been paying for a lot of things that were absolutely unnecessary. What can be done in knife manufacture, can be accomplished in other lines.

At first, certain difficulties may be met with, but nothing worth while was ever accomplished without a certain amount of trouble. Once let the idea take root among manufacturers and our foreign trade will develop, for we will then be more able to compete with other nations, where the scale of prevailing wages is much lower than that in Canada. The results of the coming convention will be watched closely, and it is more than likely that valuable experiences in standardization will be related at that time.

Do Your Own Thinking

THE MEN who have made a success of life are those who have been brave and energetic enough to get away from the beaten track. Anyone can be a routine worker, but it takes courage and initiative to step into fresh fields of endeavor.

When people speak of a trade or profession being overcrowded they seldom realize the real root of the trouble. It simply means that a large number have become fairly proficient in some particular line. True, they may have mastered a trade, but they are routine workers nevertheless, or at least the large percentage of them are. The really worth while men are seldom out of employment, for they are so far above the average in that profession, that they are invaluable. In other words, rather than be content to follow a regular routine, they have done some thinking for themselves, finding new and more efficient ways of performing the same tasks.

Take the case of the chemist. He has standard tests which he can follow up to obtain certain results, but discoveries of importance are not made in this routine fashion. Edison would never have become a world-famed personage had it not been that he refused to stick to routine work. He delved into new methods, used his brain to advantage, and even when results were not encouraging, kept faith in his ideals.

We all need some of the Edison spirit. Get away from the idea that because a task was completed in a certain fashion a year ago, yes even a day ago, that it must be done that way for all time. No matter what line of industry you are in, make up your mind to be a searcher, rather than a plodder. Think for yourself, find out some better method of performing your daily tasks and success will automatically follow.

The process is also eminently adapted to the welding of side sheets and fire boxes of boilers, and the cutting torch is extensively used for cutting out patches, removing rivets and stay bolts.

It would be difficult to mention an industry which has developed to such an extent as the one under review, and its possibilities are practically unlimited. It would therefore, appear that machinists, garage owners, etc., would do well to see that they keep up with the developments of the process in order that they may not be handicapped in the never ending competition to which they are subjected and may be on even terms to compete with their business rivals.

Pay as Promptly as Possible

FINANCING is not an easy matter just at present. In fact, some firms frankly admit that the reason they cannot pay their bills as promptly as they would like to, is because they in turn cannot collect from their customers. Unfortunately some who do not really need to do so, are taking advantage of the situation, and are issuing notes, and retarding the payment of same as long as possible.

When any number of firms start this practice, it is not long before the majority of the business community is following suit, financing on long terms instead of prompt acceptances. This is bad business, and while every leniency necessary should be extended to worthy institutions, who may be rather pressed for ready cash at the moment, still, on the other hand, no financially able firm should hold back payment when they are able to pay their way. Let a few of this type start the ball rolling, and it would not be long before collections would become easier all around.

Business Conditions Are Picking Up Slightly

Small Tools and Supplies Show Good Volume—Machine Tools Fairly Active—Non-Ferrous Metals, Scrap and White Metals Are Quiet—Pig Iron Not Active But Business Has Better Tone

BETTER FEELING NOTED ON MARKETS

THE bright spot on the Canadian market at present is the small tool and supply business. From figures compiled, we find that the month of January, 1922, was better than November and December, 1921, put together, and that February was 20 per cent in advance of January. From the number of orders received so far this month March should pass last month's figures.

Business continues to improve as the season advances, but not any more than was reasonably expected. This is especially true of the steel market, for although the month of February was better than January, the figures now totalled show merely the seasonable increase.—The outlook for March indicates further slight improvement in sales. As a result of the higher prices for farm products, and the feeling that there will be a good demand at those advanced prices for this year's crops, there is a marked change in sentiment among business men.

A few reductions in price have occurred during the week on Canadian markets. Copper lines are down about 25 cents per ton in Montreal, although Toronto prices remain stationary. Galvanized wire products and nails are also down from 15 to 25 cents. While these are not very important changes it shows that the tendency is downward, not upward.

Machine tools remain quiet, but some dealers are securing a fair amount of orders by aggressive sales methods. Oils and waste are in fairly good demand, the latter having shown an improvement in February, over the former month.

The activity along the waterfront in Montreal has lent an impetus to trade in that locality, and boiler tubes are featuring this market, together with other marine requirements.

Pig iron is very quiet, also non-ferrous metals and scrap. Until foundries pick up no improvement is looked for.

There has been a general falling off in the demand for steel products in the States. This is practically the first recession since the beginning of the year. Shading continues on this market, and on an attractive order bars, shapes and plates can be bought at 1.35 cents, Pittsburg against the former figure of 1.40 cents. Pipe is also being shaded more extensively. The demand for wire nails is good, but the demand for wire products, such as barb wire and fencing is poor. Pig iron basic is now admitted to be $17.75, although some held out for $18. Bessemer is $19, foundry iron between $18.75 to $19, and Connellsville furnace coke between $3.25 to $3.50. Demand for coal has dropped off during the past ten days.

Toronto

March 8.

ALTHOUGH we cannot point to any sensational improvement in the local market since our last report, we can, without doubt, say that every week sees a further step up so far as increase in business is concerned. Dealers are thoroughly convinced that the market will climb slowly but steadily from now on, and of course, as the season advances, the improvement will be all the more noticeable.

Iron and Steel. Take for example iron and steel. January was slightly better than November or December, February gained a little on January, but from present outlook March will show a decided step up over last month. Of course, in the iron and steel field this is to be expected, as with the good weather coming on builders are getting ready for the spring. Dealers feel, that while commercial building, in other words, building for speculative purposes, will not be as brisk as formerly, public buildings and garages will be erected in fair numbers.

Another thing that is helping the iron and steel trade is the fact that manufacturers' stocks as a general rule are down almost to nothing. This is clearly shown by the number of orders placed on the condition that immediate delivery is given. A few orders are being placed on second quarter business, but very few. Prices remain unchanged, and shading still continues where the order is very desirable. No particular line is featured, the demand being general. Following are existing quotations in the Toronto field:

Iron bars	2 75
Steel bars	2 75
Reinforcing bars	2 75
Steel hoops	3 75
Tire steel	3 00
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in. base	3 25
Small shapes	3 00

Pig Iron. There still remains a dull market for pig iron. The price has not changed, being still quoted at $27.15, but as mentioned, last week, a slightly better price is usually obtainable when the quantity ordered is of large, or even medium sized proportions. Foundries are dull, and until manufacturing plants secure better business this condition is likely to continue. It is a generally understood fact that the pig iron demand will not pick up until manufacturing lines improve.

Non-Ferrous Metals. These metals continue dull, brass and copper being particularly weak. Red metal is plentiful, but no buyers can be found. White metals are also inactive, and in fact there is a somewhat depressed feeling throughout this whole market. There has been no change in prices, dealers feel as there being no use for the metals ing that price is not the trouble so much with business so quiet in the lines usually requiring them. Following are present prices.

Lake copper	17 00
Electric copper	16 75
Castings, copper	16 50
Tin	34 00
Spelter	7 25
Lead	6 75
Antimony	8 00
Aluminum	27 00

Scrap Metals. Here again we have a quiet market for the reason already stated. The demand is simply not there so that dealers have to be content to hold on to their stocks for the present. One large user is not expected to enter this market for some time, adding to the already quiet feeling in scraps generally. Following are existing prices:

Copper, light per 100 lbs.	8 00
Copper, crucible	10 50
Copper, heavy	10 50
Copper wire	10 50
No. 1 composition	8 50
New brass cuttings	6 00
Red brass turnings	6 00
Yellow brass turnings	4 75
Light brass	3 50
Medium brass	4 50
Scrap zinc	3 25
Heavy lead	4 00
Tea lead	3 00
Aluminum	10 00
Boiler plate, per gross ton	9 00
Heavy melting steel	9 00
Axles (wrought iron)	17 00
Rails (scrap)	10 00
Malleable	10 00
No. 1 machine cast iron	18 00
Pipe, wrought	7 00
Car wheel	18 00
Steel axes	15 00
Mach. shop turnings	4 00
Stove plate	16 00
Cast boring	3 00

Machine Tools. A very spotty market exists in machine tools. Some dealers are getting a fair amount of orders, and claim they are doing as good as can be expected under present circumstances, but others again feel that the market is down and out for some time to come. Striking a happy medium would be about right, for while conditions are bad for some, others who are going out after the business are finding a certain amount of it. This is well exemplified by a conversation which Canadian Machinery overheard when on a call. "I am much impressed by their attitude, I think they will buy. I'll write them a letter tonight," remarked a salesman to his manager. "Write," yelled the executive, "write be ———, get a time table look up the first train, get up there and

and land the order." Naturally the firm we refer to, say that all things considered they are doing nicely. It's the man who goes after the orders that gets them these days.

Small Tools and Supplies. This section of the market shows added improvement every week. It is a healthy growth being gradual and in all lines. For example here is a statement given to Canadian Machinery by one dealer, and based on actual figures in the ledgers. January, 1922, was better than November and December, 1921 put together. February was 20 per cent. better than January, and according to the way March has started, a further gain will be made this month. No one line is in demand, and the orders are coming in from a scattered territory. The very nature and size of these orders show that a hand to mouth buying policy still exists, and that stocks in the tool stock room in manufacturing plants must be very low.

Oils and Compounds. A slight reduction in price has occurred in oils this week, black and petroleum oils being the ones affected. Black oil dropped from 21 cents to 19 cents, and petroleum from 10.40 cents to 9.90 cents.

Miscellaneous. Wire nails and galvanized wire products have dropped a little in price, this ranging from 15 to 25 cents. The demand for waste is slightly improved, and those engaged in this line are not complaining. Steel pipe is moving at a fair rate, but other lines such as lead sheets and copper products are not very active. It is a highly competitive market, and dealers have to be right on their toes to land orders.

Montreal

March 8

THE IMPROVED tone in the general conditions that made itself noticeable last week is now a little more in evidence. It will, however, be remembered that merchant bars and structural steel were still quite sluggish and no perceptible change in these commodities has been noted. This is, of course, the result of the quiet times being experienced by those manufacturing and contracting activities that form the chief sources of consumption of these materials. This quiet period only indicates that the pendulum, which swung from the side of great activity to the other side of practical stagnation, has not yet swung back far enough to bring these plants in the sphere of increased activities. Our trade locally, however, is improving, and there is every indication that the coming season will be more encouraging than in 1921. No one expects that there will be a boom year, but we do believe that there will be a marked improvement over present conditions all along the line.

The cause of the better trend of business lately is the activity along the water-front. Spring always lends a certain impetus to trade, but in a city situated as is Montreal, where the harbor activities are tied up entirely for three or four months every year, the direct and indirect results of the approaching spring have a much greater influence than they would have if the city had a harbor that was open twelve months of the year.

Iron bars, base, Montreal	2 75
Steel bars, base, Montreal	2 75
Reinforcing bars, base	2 75
Steel hoops	3 75
Tire steel	3 00
Spring steel	6 00

Boiler tubes are again featuring the market, together with other marine requirements. Sheets and plates are also moving in a somewhat better manner. The prices of all steel products remain the same and there is a tendency for prices to be firm. Very few jobbers have much of a stock on hand. The rumoured reports of a coal strike on April first are entering into the situation to a certain extent. Most jobbers believe that when April arrives there will be an increased demand over the present, and if the strike tends to tie up transportation to any great extent, and supplies cannot be obtained, a shortage will occur which will send prices soaring. Whether the strike will actually take place is another question.

Pig Iron. Very little change has been reported in the pig iron business. The demand has not materially increased, and the hand-to-mouth method of buying is much in evidence. An example of this was noted last week, when one firm had a little run of orders that completely exhausted their supply. After a hurried canvass of the dealers it was found that not one had a car of pig iron in stock. The situation was taken care of by buying a few tons from one of the consumers in the city and ordering a car by wire with the usual instructions for car number, etc., to be forwarded to consignee, trace by wire and such other practices that were of common occurrence a couple of years ago.

The survey of the city resulted in uncovering the fact that there is not more than three or four hundred tons of pig iron in the whole of Montreal. The prices are the same, and producers claim they lose money on every ton of iron they sell at prevailing figures. There does not appear to be any changes in quotations contemplated, and the prices of American iron are such that Canadian figures come to about the same thing. Thus, if prices on the Canadian product were advanced, it would result in the importing of American iron which can be placed in foundries at about the same figure that is being asked by Canadian producers today.

Machine Tools and Supplies. There is no increased activity in the sales of machine tools. Dealers are, however, feeling somewhat better than they were a short while ago. It was pretty generally understood that there was a large number of remanufactured and second-hand tools for sale. A very careful survey of the situation on both the Canadian and United States side of the line has resulted in the finding that there is only a limited number of these tools, and that they are being slowly absorbed. In fact at the present time there is no more than would be ordinarily on the market in normal times. This means that when the demand does appear it will be new tools that will have to move. Prices have not changed a great deal as there is not enough business to warrant same, although the tendency is for quotations to be gradually reduced.

The small tool business still keeps on slowly improving from week to week, and the revenue from this department really forms the major portion of the total revenue obtained by many jobbers. Prices are reasonably firm, but are being reduced slightly from time to time as business improves. In case of large orders, which are few and far between, a slight discount can usually be obtained.

Non-Ferrous Metals. Copper weakened still further during last week, and is at present being quoted at a lower figure than has been seen for many months. Quotations for other metals are the same and business generally is slightly improved over last week. There have been no outstanding events in this market, and the improvement in Canadian exchange has made Canadian funds a little stronger in New York. Following are Montreal quotations on non-ferrous metals:

Lake copper	16 75
Electric copper	16 50
Castings, copper	16 25
Tin	34 50
Spelter	7 25
Lead	6 75
Antimony	8 00
Aluminum	27 00

Scrap Metals. Very little activity has been evident in scrap metals for the last week and quotations have not changed to any extent. Dealers still claim that something approaching a shortage exists, and that the prospective consumer is willing to take his chances on this shortage materializing. Following are Montreal quotations on scrap metals:

Copper, light	8 00
Copper, crucible	10 50
Copper, heavy	10 50
Copper wire	10 50
No. 1 machine composition	8 50
New brass cuttings	6 00
Red brass turnings	6 00
Yellow brass turnings	4 75
Light brass	3 50
Medium brass	4 50
Scrap zinc	4
Heavy lead	4 00
Tea lead	3 00
Aluminum	10 00
Boiler plate	9 00
Heavy melting steel	12 00
Axles (wrought iron)	20 00
Rails (scrap)	12 00
Malleable Scrap	12 00
No. 1 machine cast iron	19 00
No. 1 machine cast iron	19 00
Pipe, wrought	6 00
Car wheel	18 00
Steel axles	18 00
Mach. shop turnings	6 00
Stove plate	16 00
Cast boring	6 00

Pittsburg

March 8, 1922

PITTSBURG, (Special to Canadian Machinery).—On the whole the buying of steel products has fallen off somewhat in the past week, this being the first recession since the market began to grow more active, at practically the beginning of January. The decrease is not seen in every line, but it is moder-

ately general. However, the experience is too short to justify any conclusion that the market has turned quiet, for there are naturally ups and downs. According to the best judges a period of 30 days should be allowed to elapse before any definite judgment is formed.

The quieter market just at the moment, sounds a proper note of warning and emphasizes a fact that has already attracted some attention, that the increase in demand during January and February was very rapid indeed, surprisingly rapid even to those of most sanguine temperament. Many steel men were remarking in substance that they just wished the improvement would continue.

The magnitude of the increase in demand that has occurred is brought out by comparing ingot production rates. The rate now is about 29,000,000 gross tons a year. Last July, at the low point, it was only 10,000,000 to 11,000,000 tons. It was stated in well posted quarters that the liquidation of stocks of steel in the hands of buyers was practically completed by October 1, and production in October and November, representing last autumn's seasonal demand, was at 23,000,000 tons a year. Then at the end of December the rate was down below 18,000,000 tons, perhaps no more than 16,000,000 tons in the holiday week. Production during the entire year 1921 was approximately 19,500,000 tons. With a rate of 29,000,000 tons the first week in March one can see what a sharp increase has occurred.

Early in January there developed fresh price cutting, competition becoming particularly severe, even for relatively small orders. In some lines it seemed as if there were no order so small that some mill was not willing to cut the "regular" or open market price a trifle in order to get that tonnage. As stocks in the hands of buyers were thoroughly depleted, and such attractive prices were being quoted, it would not be unnatural for buyers to replenish their stocks in a moderate way, to a level that would enable them to conduct their business efficiently and economically. Some of the heavy production of the past few weeks may have been on this account. This is merely deduction or theory, for it should be noted that the mills do not admit that their customers have been stocking at all. According to the statements commonly made by the mills the evidence of their order books is that the steel shipped from day to day has been going immediately into consumption.

However this may be, in detail, it is quite certain that there is no speculative stocking. No tonnage is being accumulated that will have to be liquidated in anything like the style of last year's liquidation. Production may increase some more or it may in time go off somewhat, but it is inconceivable that it should ever again get down to the phenomenally low rate of last summer.

Steel Prices. The fact that the price of a given finished steel product is low by any comparison is no criterion that it will not decline farther or that it has reached the rebound point. This is exemplified by a comparison between black and galvanized sheets on the one hand and bars, shapes and plates on the other. At the beginning of last December sheets stood at 3.00c. for black and 4.00c. for galvanized, while bars, shapes and plates were 1.50c., with possible concessions on attractive orders. By statistical comparisons as well as by estimates of production costs prices for bars, shapes and plates appeared lower than prices for black and galvanized sheets. Yet the history of the market since then is that bars, shapes and plates dropped recently to 1.40c. as an open quotation and now 1.35c. can be done on a moderately attractive order, while sheets have stayed at the same old prices, for more than three months. One theory to account for this disparity is that in bars, shapes and plates, mills have been feeling that prices were already so low that they could hardly go much lower, and to make lower quotations might cause some producers to quit, thereby arresting the decline, while on the other hand sheets might find they had quite a distance to fall if mills once began tampering with prices. The manufacture of sheets at 3.00c. and 4.00c. may not be particularly profitable, but at any rate losses can be avoided, with a fair operation, while no mill can possibly come out whole on bars, shapes and plates at 1.35c. The mills are losing a large part, in some cases perhaps all, of their overhead and general expense.

Pipe is being shaded somewhat more extensively, the 2½ per cent. extra discount frequently given by independents, from the regular prices of the leading interest, having extended to 5 and 2½ per cent. in many instances. The extra 5 per cent. is equivalent to an average of between 1½ and 2 points in the discount list, hence it is thought in some quarters that the published discount list will have to be revised in the near future. The present card carries a basing discount of 71 per cent.

Wire Products. Demand for nails is quite good, while demand for other wire products, particularly barb wire and fencing generally, is very poor. Prices of wire products are steadier than a week ago, as the special price of $2.40 on nails has become fairly general, without leading to fresh concessions on large lots, while plain wire seems to have stiffened up some, report having it that 2.25c. is rarely if ever shaded.

Pig Iron. While throughout February the merchant blast furances were claiming that basic pig iron was $18, valley, the average computed by W. P. Snyder and Company, taking all sales of valley iron in lots of 1,000 tons or over shows that no such sales were made during the month except at $17.75, and that may be taken as the quotable market price. Bessemer has sold at $19 and $19.50, depending on tonnage. Foundry iron, which was cut in a sale recently reported to $18.75, valley, has been selling well in small lots at the full $19 price.

Connellsville furnace coke has no more than held its recent advance, to a range of $3.25 to $3.50. It seems that one can pick up a moderate tonnage at $3.25 but a large lot might require a higher price, as operators will not blow in ovens unless assured of a demand for a reasonable time, hence the spot buyer must depend on the floating supply. Foundry coke has experienced another advance and is now firm at $4.25 to $4.75, depending on brand, which makes a total advance in about three weeks of 50 cents a ton. As a rule the coke that used to sell at $3.75 now brings $4.25 and the coke that used to sell at $4.25 now brings $4.75.

Demand for coal has fallen off in the past ten days, either because buyers have changed their minds about there being an important mining suspension April 1 or because they have accumulated all the stocks they think necessary.

The Pittsburg Steel Company and Jones & Laughlin Steel Company, absent from the scrap market for several months, have bought more than 10,000 tons of heavy melting steel scrap in the past week, the price reported as paid being $15, delivered.

"MYSTERY OF ROARING RAILS"

On many of the railway systems of the world the phenomenon of "roaring rails" has been a too familiar trouble to engineers. The surface of the rails developed ridges at regular distances of an inch or so, and these corrugations led to excessive noise and vibrations. On electric tramway systems the same trouble appeared in even greater degree; frequently the noise was so excessive that the rails had to be ground flat at great expense—only to reveal fresh corrugations as soon as the traffic was resumed. All sorts of explanations were offered and for a long time the precise cause of the trouble remained a mystery. Now the problem has been settled by a series of experiments carried out by a committee of British experts on a tramway subway in London, where the rails and track could be altered freely so as to test the various explanations put forward. The conclusion reached is that vibration has nothing to do with the case and that the real cause lies in the action of a very heavily loaded wheel running along the rail. This action makes the material of the rail surface "flow" into waves or corrugations very much as an ordinary road surface flows into waves under the action of a steam roller. The remedy therefore lies in the use of harder rails and, where possible, of larger wheels.

There are more passenger cars owned in Ontario than in any country in continental Europe, South America, Africa or in all Australia, and the fact that per capita only three cities in the world of a half million or more population are as motorized as Toronto. London, England, New York, Paris and Chicago in proportion to their population lag far behind this Queen city in numbers and values of motor vehicles owned by citizens.

SELECTED MARKET QUOTATIONS

Being a record of prices current on raw and finished material entering into the manufacture of mechanical and general engineering products.

PIG IRON

News From the Industrial Field

The York Sandstone Bridge Co., East Toronto, Ont., is asking for prices on a horizontal tubular boiler.

Preliminary work on the plant of the Three Rivers Pulp and Paper Co., which is capitalized at $3,000,000, will be started in March, 1922.

The mill owned by the Canadian Lumber and Timber Co., Vancouver, B. C., was destroyed by fire with a loss of $110,000. It will be rebuilt at once.

The City of Toronto has had plans prepared for a steam heating system for the live stock arena at the Exhibition Park to cost $100,000.

A Nottingham, England, firm handling all kinds of machine tools, new and second hand, for shipyards, engineers, and kindred trade invites correspondence from exports.

Hopes are entertained that a permit will soon be granted to construct the proposed bridge over the Niagara River between Fort Erie and Buffalo.

The cartridge factory of the Dominion Arsenal at Quebec was destroyed by fire last week. About a million rounds of small ammunition were destroyed.

Barnett, McQueen, Co. has received a contract from James Richardson & Sons for the erection of a million and a half bushel storage annex to the existing grain elevator at Port Arthur.

E. D. Mitchell, special representative of the Alfred Herbert Co. and associate companies, visited the Toronto office at Jarvis St., a few days ago. Mr. Mitchell paid the Canadian representatives this visit prior to his return to England.

The Ford-Smith Machine Co., Hamilton, Ont., who recently started to make imers for Ford cars, report very good business in this line. They also look for further demand now that the motoring season is opening up.

Seattle retailers through the Retail Trade Bureau of the Seattle Chamber of Commerce, have announced that Canadian money will be accepted at par for the first time since the unfavorable situation created by the war.

An old established business in Birmingham, England, is well situated to deal with the following metals if prices are satisfactory; copper, lead, zinc, nickel, aluminum, babbitt, metal, brass and bronze.

British Smelting and Refining Co., of 120 St. James St., Montreal, announce that on May 1st they will move into new offices in the Canada Cement Bldg., Phillips Square, Montreal.

The machine shop of the Home Logging Co., Courtenay, B. C., was almost destroyed by fire recently. The shops were equipped with machinery valued at about $50,000.

A prominent tap and die manufacturer told Canadian Machinery that the past two or three weeks have shown a decid improvement in the volume of business closed. Orders are coming in faster, and the number requested on such orders is also increasing.

The report has been submitted for a water supply system including steel reservoir pumping equipment, etc., to cost about $900,000. The programme called for an expenditure of $90,000 initially. This is quite some expenditure for Todmorden.

The Board of Education, London, Ont., decided upon a building program this year with an expenditure of approximately $700,000. Of this amount, $120,000 has been set aside for an auditorium, gymnasium, and additional class-rooms for the Technical and Arts Schools.

R. C. Douglas, of the Norton Co. of Canada, gave an address on the subject of "Grinding," at a meeting of the purchasing agents in Hamilton a few days ago. B. C. Ball, of the Steel Co. of Canada, spoke on the coal situation at the same meeting. After the regular meeting and dinner, the plant of the Canadian Westinghouse was visited.

The census of Canada's population taken in 1911 totalled 7,206,643. The figures as taken for the year 1921 show a total of 8,769,489. These figures show an increase in all provinces with the exception of Prince Edward Island, the Yukon, and the North West Territories.

The Office Specialty Mfg. Co. has been incorporated to take over the plant and business now carried on at Newmarket, Ont., by the Office Specialty Mfg. Co., Toronto, to manufacture office furniture, vaults, filing cabinets, desks, etc., with $1,000,000 capital stock.

The Empire Cotton Mills, Welland, Ont., has decided to erect a dye mill adjoining its present plant in Welland at a cost of $200 000. Between 150 and 200 employees will be added to their present staff. Construction will start within six months of the passing of the local industrial by-law.

A plant will be built in Galt by the International Tank and Silo Co. A four-acre site has been purchased and a one-storey building 200 feet by 120 feet will be erected. The Galt company will manufacture the same products as those made by the Endlock Mfg. Co., of Des Moines, Iowa. Both companies are controlled by Canadian interests.

One of the best known among high-grade English cars is the Vauxhall, which was in course of being introduced into the Canadian market when the war broke out. Canadian business will be handled by a branch office—Vauxhall Motors, Limited, 188 King St., W., Toronto, Ont., with agents and distributors in the principal cities throughout the Dominion.

The Hon. W. S. Fielding, Canada's Minister of Finance, has had a lengthy conference at the Commerce Department in Washington, the object of which it is understood was to canvass the possibilities of the reciprocal trade agreement between Canada and the United States.

The preliminary survey of the manufacturing industries of the Province of Quebec for 1919, conducted by the Dominion Bureau of Statistics, indicates a substantial growth in potential industry. The number of establishments for the period from 1917-1919 was an increase of 1,061. Capital increased $113,500,000. Number of employees decreased 5,500. Production increased $150,000,000.

One evidence of the revival of business conditions in Orillia is the fact that the Orillia Worsted Co. will immediately enlarge its factory premises in order that fifty more hands may be employed. At present the factory is employing 120 hands which is about a full staff, but the demand for the factory's products is such that 40 or 50 more can be profitably employed almost immediately.

The telephone was invented by Dr. Alexander Graham Bell, a Canadian scientist, and Canada has nearly one million telephones, representing a capitalization of one hundred million dollars. The telephone companies spend annually for research, the results of which are all about us, a sum greater than the total income of many universities, and the enormous amount saved by the use of the telephone is incalculable.

Birmingham Motors, Ltd., Peterboro, Ont., has been organized under the Canadian charter and has acquired the Dominion rights for the manufacture of the Birmingham car now being manufactured at Falconer, New York. The Hope plant in Peterboro has been taken over and the manufacture of the car is to begin in a few weeks. The company has contracted for the past upon its own specifications and is not buying any equipment.

Prof. H. E. T. Haultain of Toronto, who is attending the meeting of the Mining Institute in Ottawa, will describe some novel experiments on Tube Mills. The striking feature of this work is an interesting film, taken at the speed of 120 photos per second by means of an ultra rapid camera. Mr. Haultain has been working for three years under the auspices of the Scientific Research Council. This is the first instance of the application of high speed photography to research in Canada, and it is stated that the method gives promise of great possibilities.

Business this year has been much in advance of the corresponding period in 1921, according to officials of the Buhl Stamping Co. Since January 1, the company has been employing 35 men on full time, and is now working on several big orders.

At the annual meeting of Canada Foundries and Forgings, held at the Brockville office on February 28th, Hon. W. J. Shaughnessy of Montreal retired as a director, at his own request, and was replaced by Harry B. Housser of Toronto. Mr. Housser is connected with an influential financial house in Toronto.

L. A. Paddock, vice-president and general manager of the Canadian Bridge Company, Walkerville, declares that things are now on the upward trend, and that hopes of revlving industry can now be reasonably entertained. He declares that prices of raw materials have now reached almost a pre-war basis, and that good business may be looked forward to this year.

Up until the middle of January, the Walker Twist Drill and Tool Co. was working only four days per week, but since that time the working week has been increased to six days, five of ten and a half hours and nine hours on Saturday, and the firm is being kept at capacity production, filling orders already on hand.

Through the efforts of the Border Chamber of Commerce, the Canadian Aluminum and Brass Co., is opening a branch in Windsor, in a part of the plant occupied by the Dominion Motor Castings Co. The company is affiliated with the General Aluminum and Brass Co., Detroit, and the president, J. P. Carritte, states that actual work will start at the new plant about the middle of March.

Brampton, Ont., had the most costly fire in its history on February 24th, when part of the Pease Foundry was destroyed. Superintendent J. Davidson, who has been in charge of the plant for the past two years, estimated the damage at $150,000, the machine shop, as well as the stock room, with a heavy stock of furnaces being completely destroyed. These buildings are valued at $100,000.

The National Slag Products Co., Hamilton, of which Hon. G. D. Robertson, former Minis er of Labor, is president, is beginning construction work on its building for the manufacturing of building tiles in a few days. The necessary machinery has been ordered and should be delivered about the first of April. This plant will use slag that has hitherto been discarded and carted away at considerable expense by the Steel Co. of Canada. Speaking to Mr. Hobson, president of the Steel Co., regarding the above information, he told Canadian Machinery, that while the using of the formerly discarded slag was perfectly true it was not as large a saving as one might expect, as on'y a very small percentage of the slag at their plant was used by the National Slag Products Co., this being of the granulated variety.

The article on Overcoming Defects in Drop Forge Work, which appeared in March 2 issue was a paper by the author, to be read before the March Meeting of the American Society of Heat Treaters.

A. H. Milne, British Trade Commissioner for Canada and Newfoundland, announces that a British firm in competition with the American manufacturers has secured a contract with the provincial government of Manitoba for the installation of six-thousand-line automatic telephone exchange for the Fort Rouge district of Winnipeg. The contract amounts to about $483,000.

Twenty-two Canadian manufacturers have arrived at Kingston, Jamaica, for a visit which has as its object the fostering of trade between the two countries. They were given a hearty welcome by the delegation of business men who expressed the hope that a large portion of the trade with the United States would be diverted through the Dominion under the Preferential Tariff.

Wm. Kennedy & Sons, Owen Sound, are converting the tug Alexandra from a side wheeler to a single screw propellor for the Upper Ottawa Improvement Company. The boat has been and will be used for towing large rafts of logs. She is 150 feet long, 26 feet beam and 14 feet draft. The change calls for installation of propellor, rudder, stern frame, bearings, steering gear, and main shaft.

Rebuilding of furnaces and extensive additions to the plant of Pilkington Bros. at Thorold, Ont., are responsible for a temporary close down of the plant, according to a statement issued by J. E. Harrison the Canadian general manager of the company. Coupled with that statement, Mr. Harrison declared that he was looking forward to a revival of the building trade that would control to an extent the speed with which the alterations would be accomplished.

There is a fleet of fifty freighters in Midland harbor for the winter season and necessary repair work and overhauling is giving considerable work to such concerns as the Midland Engine Works, Midland Shipbuilding Co. and the Georgian Bay Shipbuilding and Wrecking Co. Three of the French freighters recently purchased for the Playfair interests are tied up here. Numerous tugs and other small craft are also being made ready for the approaching navigation season.

Interviews with heads of local industrial plants in Windsor, Ont., lead to the conviction that an industrial reawakening is imminent. The consensus of opinion among industrial leaders seems to be that the bottom of the depression has been sounded, and that better business will ensue immediately. This condition is attributed by the industrial leaders to a general decrease in the price of raw materials, and the fact that buyers are eager to take advantage of this circumstance, with the result that trade will be revived to a great extent.

The reductions in prices announced during the recent automobile show at Detroit, Mich., were important factors in bringing about the surprising rush of business which is rapidly swinging all the big factories into their full stride, reached before the usual boom. Managers point out that the full effect of the public interest has not been felt. Thanks to highway construction all over the country and particularly about big cities, urban orders have broken all records since early in December.

The Durant Motors of Canada turned out their first Canadian-made car at their Leaside plant on the morning of March 1st. Total production for the day amounted to ten cars, and it is expected that the output will be brought up to 50 cars daily within a few days. The Leaside plant, it is stated, is now equipped and ready for quantity production, and all of the cars to be absorbed by the Canadian market will be manufactured there. The present year's schedule calls for between 12,000 and 15,000 automobiles.

Canada Electric Castings, Limited, are building on the site of the foundry of Canada Electro Foundries, destroyed by fire, a two story foundry 250 ft. by 50 ft., for which they are using the steel frame and other material bought from the Baldwins when they dismantled the Collingwood Steel foundry. W. H. R. Burrows, the manager, states that he hopes to have his new plant in operation by the middle of April. He is specializing in steel castings, including grinding balls, for the mining and concrete industries. His equipment will include 2 electric, three phase furnaces of the Heroult type, with Volta attachments, giving him a daily capacity of 18 tons.

H. B. Peabody, vice-president of the Peabody Corporation, announces that his firm is planning a real industrial revival, and to this end, all former employes, who were laid off during the period of depression, are being offered employment. Mr. Peabody states that, within a short time, the staff at the Walkerville plant will be increased by 50 percent. The statement declares that, from the standpoint of the firm, business conditions in Eastern Canada are as favorable as they were in 1919, and that an increase in the price of wheat in the West will make a material difference in that section.

Electrical energy is the power of the present and is likely to become more important year by year in the life of the Canadian people. A writer in Pulp and Paper magazine stated lately that the investment in electrical development of Canadian water powers is already $475,000,000 and will be not less than a billion dollars by the year 1940, if the present rate of growth in installation continues. The power now utilized represents coal that would cost $148,000,000 yearly. By 1940 it would be necessary to burn 42,000,000 tons of coal yearly at a cost of $336,000,000 to provide the power this writer estimates will be produced from Canadian waterfalls.

Canada heads the list of countries from which the United States imported iron and steel during the year 1921, the report which has just been made public discloses. Importations from the leading countries during the year were: Canada 24,079 tons, Belgium 18,529 tons, Sweden 5,507 tons, China 4,610 tons, Germany 4,282 tons, United Kingdom 3,385 tons. Of the total importations from Canada 21,251 tons consisted of steel rails. Canada and Belgium furnished 65% of the total exports for the year.

A large contract has been signed which calls for 200,000 h. p. and has been made with the Shawinigan Power Co., by a United States group, presumed to be the Aldred group with which it already has a connection through its directory. The Shawinigan Co. is also reported to have secured control of the Southern Canada Power Co., which operates on the south shore of the St. Lawrence River and it is believed that the transmission privileges of this company will be used for the transfer of the new power when developed to the border.

Toronto recently had a Made-in-Canada exhibition of goods with a view to stimulating the use of Canadian products and now one is to be held early in March in Montreal at Almy's Limited. It is the first of its kind ever promoted in Montreal and the seven spacious floors of the department store with an area of 300,000 sq. ft. will be fully occupied by the exhibits. Approximately 225 Canadian manufacturers will have their handicraft on display and every phase of Canadian industry from the products of the tiniest loom to the output of the largest factory will be represented.

It was announced at the inaugural meeting of the 1922 Board of the Canadian National Exhibition, Toronto, that still another new building is in prospect for the grounds. The textile interests are the latest industry to favor the segregation principle and to take up the question of separate housing for their exhibits. For some time past the machinery manufacturers have been negotiating for a building under the same terms as the pure food interest, to exhibitors to contract for space for a period of ten years or more at a figure to care for all interest, reserve funds and maintenance charges.

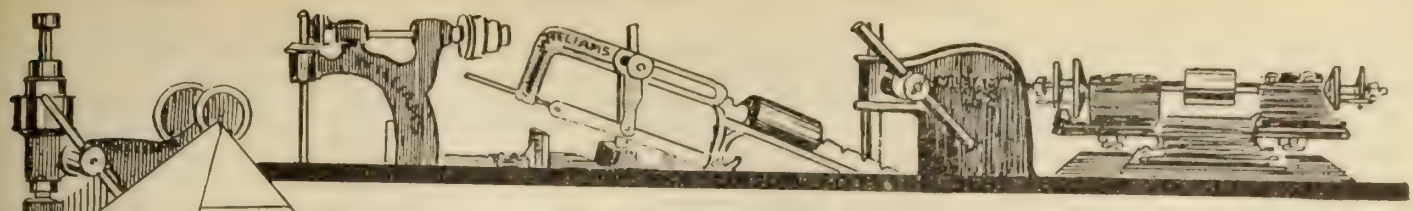
Electro-Castings, Limited, Collingwood, expect to have their foundry ready for operations early in April. W. T. Stephens, manager, is supervising the installation of a two-ton electric furnace of his own design. It will have a capacity of 12 heats in twenty-four hours. Production along general and special lines, will be in grey iron, hard iron and semi-steel. Mr. Stephens has had experience with electric furnaces. He was formerly with the Canada Electric Castings, Limited, Orillia, and operated a foundry for Wm. Kennedy & Sons, Owen Sound, in the building now occupied by the new company. He is assured of an abundance of power, and given that he declares the prospect to be very encouraging.

An announcement has been made by the St. Thomas Chamber of Commerce officials that the Wood Gorrie Motors, a newly incorporated company formed for the manufacture of the Warwick automobile has selected St. Thomas for the location of its plant and has engaged temporary assembly quarters in a section of the factory building occupied by the St. Thomas Boxes, Limited. At the outset the plans will be an assembling concern only using standard automobile parts.

Figures for the first two weeks of January show a marked increase in employment throughout the Dominion, in comparison with the similar period a year ago. Returns received by the employment service men to the Department of Labor from 5,800 firms with a total payroll of 641,146 persons, show that increases in staff gave employment to approximately 19,000 additional workers. This indicates partial recovery from the heavy declines registered at the end of the old year and is a marked increase over that recorded in the early part of January, 1921.

Oddfellows of the Border Cities are formulating plans to erect a $250,000 temple on Ouellette avenue, Windsor, the main street of the city. The lodge already has a temple in Windsor, but it has become inadequate for the needs of the Order, so a stock-selling campaign for the proposed new building, which will be erected early next year, will be started immediately. The temple will be built on a lot which has been owned by the Order for some years. Alderman Sam Keyser, a prominent local building contractor, is president of the organization promoting the project.

The Collingwood Shipbuilding Co., are operating at present with a force of 300 men, which will shortly be increased to 500. In addition to the construction of a sand-sucker, described elsewhere, repairs are being made on the Matthews freighters, Glencadam, and the Easton. The Str. Winona of the Canada Steamships line is also being repaired and the lighthouse and buoy ship, Grenville, department of Marine and Fisheries, is being overhauled. In the Kingston yards the Str. Keyball is having her bottom repaired. Several other ships are to be docked as soon as navigation opens for slight repairs.



William H. Randall, now managing director of the Neptune Meter Co., Toronto, returned home recently after a trip to New York, where he placed orders for some special machinery with the object of extending the company's plant at 1197 King St., W., Toronto. For the past two years practically all of the company's standard makes of meters of the sizes that are usually in demand by Canadian municipalities have been manufactured in Toronto, but the large meter and all special types have been imported from the Neptune Meter Company's plant in the United States. The object of the proposed extension is to enable the Canadian company to make practically all sizes and types for which there is likely to be any demand in Canada.

The new building planned by Ontario Hydro Electric Commission on University Avenue, Toronto, will cost approximately $500,000 and will involve about 450 tons of steel. It is understood that the Robert Redford Co. is considering the erection of an office building near Bay and Wellington Sts. This building erection is under contemplation but a definite decision is not expected for several weeks at least. The highways department of the Ontario Department of Public Works is proceeding with some bridge construction. A larger programme of bridge construction is understood to be under consideration.

The Midland Engine Works, manufacturers of steering engines and gasoline marine motors, are adding to their line a marine motor of the Scripps type. For the present, they will build them in four cylinder size, 25 to 40 horse power adaptable to cruiser types of boat from 35 to 40 feet or for speed boats 20 to 25 feet length. J. Bruce Hanly, the manager, who is an authority on motor and water boat construction, states that for a wide range of purposes this type of engine appears to him as one of the most uniform in his experience. In time he hopes to develop three sizes, two, four and six cylinder. His plans are to have 25 ready for the early summer demand.

The Georgian Bay Shipbuilding and Wrecking Co., Midland, are building for the Sauble Spanish River Boom Co., a wooden tug 70 feet in length and 15 feet beam with Heeple compound engine 10 in. x 20 in. x 14 in. stroke. This company is also converting into a floating dry dock for their own use the old wooden freighter Major. To do this they are cutting off the bow and installing a gate which may be raised or lowered as required and fitted with valves for flooding purposes. This drydock when completed will accommodate a vessel 200 feet in length and 33 feet beam. Mr. Dobson expects to have it ready for operation by the opening of navigation.

The annual report of the J. G. Brill Co., which has just been issued to the stockholders indicated that this well known manufacturing concern has now become well entrenched in its Canadian position. It was only last September that they took over the Preston Car Works, and H. D. Scully, the general manager of the Canadian Brill Co., states that in extending and improving the plant at Preston, Ont., where between 50 and 60 hands were being employed last summer, there are now 250 employees engaged and the payroll amounts to $5,000 a week and a car is being turned out every working day. Deliveries of street cars have been made in recent months to many of the outstanding cities in the Dominion. They are reported as having stated: "As a result of our experience in Canada it is our present intention to remain there permanently, and officers of the company are now investigating several sites in Toronto and elsewhere in Ontario, which would be suitable for new and larger car shops."

Is There Anything You Need in Machinery?

NAME it, and you'll find we have it. No matter what it may be we have it or can get it, and can fill your order promptly and efficiently.

We carry a full line of Boilers, Valves, Injectors, Fittings, Motors, Generators, Iron and Wood-working Machinery, Precision Tools, etc.—everything conceivable in the way of Machine Shop, Wood-working Plant, Foundry or Power House equipment and supplies.

Drop us a line asking to be put on the mailing list for our regular monthly Machinery list.

THE LUFKIN RULE CO. OF CANADA LTD. WINDSOR ONT.

A value of $92,490,000 was represented in the production of cotton textile goods in Canada during 1920 according to a report just issued by the Dominion Bureau of Statistics. The total capital invested in the industry was placed at $76,431,000.

A British Syndicate proposes the establishment of a woollen mill in the city of Victoria, B. C. says Reuter Dispatch. The company state that it is their intention to specialize in worsted materials of the highest quality and carry through the entire process from cleaning and preparing the raw wool to the production of finer grades of worsted suitings.

"Canada is coming to the front as an industrial country and in due time will make a bid for the trade of the world," stated John S. McKinnon, past president of the Canadian Manufacturers' Association, in an address before the Canadian Club, New York City, on February 26th. He further stated that as a manufacturing country, Canada was making solid progress. She was sending out manufactured goods today which before the war had been considered could not be made in Canada. The export trade of the Dominion and its relation to the United States was such that what Canada bought from the United States represented $95.00 per capita of the population, while what the United States bought from Canada represented $5.00 per head of the population.

IMPROVEMENT WILL BE STEADY AND GRADUAL

Commenting on his recent trip to England, Mr. Ford-Smith, of the Ford-Smith Machine Co., Hamilton, Ont., told Canadian Machinery that conditions in engineering circles were far from bright in England at the present time. He mentioned that in many cases, plants usually working overtime, were shut down, and that other factories were hit in like proportion.

Mr. Ford-Smith did not paint an altogether blue picture, however, for he mentioned that things were bound to right themselves and England would once more be supreme in trade. He felt nevertheless that there was a danger of over-optimism, which later might lead to disappointment. He is thoroughly convinced that any improvement will be gradual and not spectacular, and that it will be some time yet before the machine tool business becomes normal. He mentioned that he had great faith in Canada's future, and that any firm having a good reserve need not worry about what is ahead.

It is only a mttter of time, in Mr. Ford-Smith's opinion, before the real buying will once more open up. "From then on the improvement should be steady," he concluded.

Trade between Canada and China is constantly expanding, and the general trade outlook in Canada is much improved over that of one year ago, according to Canadian Trade Commissioner, J. W. Ross of Shanghai. He states that Canadian timber is constantly being placed upon the markets of China, while Canadian flour and other food products are in good demand, as are an extensive list of manufactured articles.

NEW MACHINE SHOP OPENED IN GALT

A NEW shop has opened in Galt, Ont., under the name of "Smith's Machine Shop." The owner, Cecil H. Smith, is an example of what sticking to the task in hand will accomplish. He served his apprenticeship with the Waterous Engine Works, Brantford, spending three of his four years there in the tool room. After serving his time, he went to Goold Shapley & Muir of the same city, and remained in their tool room for another nine months.

St. Thomas next appealed to Mr. Smith, and he spent two years in the railroad shops up there, three months in the Michigan Central shops, and two years in the tool room of the Pere Marirquette.

While there he took out a draftsman's course with a correspondence school, then after leaving St. Thomas returned to the same work he had left in the Goold Shapley & Muir plant in Brantford. He remained there another year and a half, in the meantime attending drawing classes in his spare time.

In July, 1911, he went to Galt to take charge of Goldie & McCullough's tool room, holding this position up to the decision to start business for himself. While in charge of the above mentioned tool room, Mr. Smith designed many jigs and tools, many of which Canadian Machinery viewed while on a recent visit to that plant. During the war Mr. Smith designed numerous shell tools, looking after making and maintenance as well.

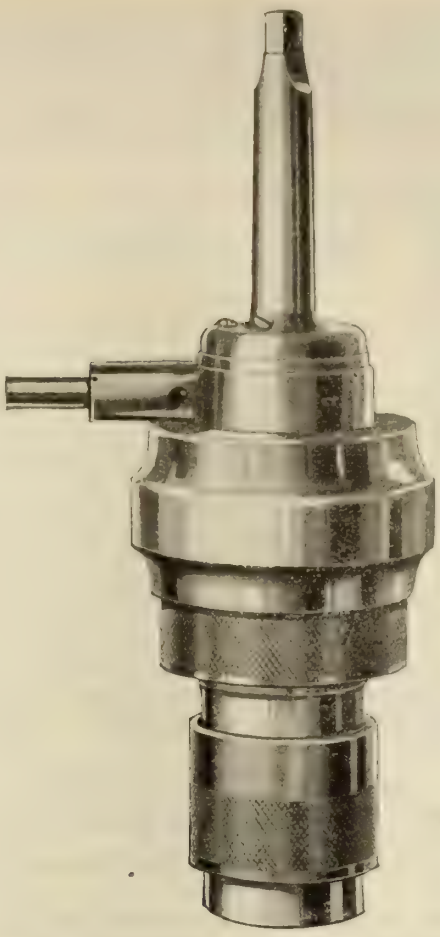
In his newly opened shop, at 34-36 Ainslie St., Galt, Mr. Smith intends to handle machine shop work of all kinds, and will make jigs, tools, fixtures, etc., or special machinery to order. He has always had the aim in mind to own a plant for himself, and by persistent plugging has now reached his ambition.

MEN OF NORTH VISIT TORONTO

NORTHERN Ontario was well represented last Friday at the Government House, Toronto, when His Hon. Lieutenant-Governor Cockshutt, entertained the men from the North. About thirty-eight municipalities were represented, these including Kenora, Fort Frances, Cochrane, Timmins, Englehart, Haileybury, South Porcupine, Cobalt, North Bay, New Liskeard, Sudbury, Sault Ste. Marie, Port Arthur, Fort William, and other localities. His Honor and Mrs. Cockshutt received.

After luncheon, Premier Drury made a short address, dwelling on the pioneer work being done by those in Northern Ontario. He emphasized the fact that to get the greatest good out of the work now being done, the North and South sections of Ontario must work in close harmony. He dwelt on the need for eliminating waste, and reforestation, also the importance of education and good roads.

Hon. Mr. Mills spoke briefly of the mining situation in the North, calling attention to the rich mineral resources of the country. Hon. Mr. Bowman also dwelt on the development work going on in the North, this being followed by speeches from Lieut.-Col. Little of Port Arthur, and Mayor Le Henp of Haileybury. Lieut.-Col. Little assured His Honor that they appreciated his bringing them all together and in a neat reply, Lieutenant-Governor Cockshutt told them how he in turn was pleased to have them down at the Government House to show them he was just the same as when in Brantford. He displayed a keen interest in their work and felt they had much to be proud of in the development which had already taken place.



WILL WORK FOR STANDARDIZATION

Standardization of industry will be the main topic at the five day meeting of the American Society of Mechanical Engineers at Atlanta, Ga,. beginning May 8. E. C. Peck of Cleveland, chairman of the standardization committee of the society, says that billions can be saved by industry by a comprehensive program of standardization. He points to Germany as the most effective instance of standardization, and said that the movement began years ago.

"Germany is making amazing propress," Mr. Peck said in the way of warning to manufacturers. "She is using standardization of industry as a link in a chain of industrial processes by which she aims once more to be a power in world trade, and she is building up an unprecedented industrial structure which must rest in a large measure on an intensive foreign trade. In no other country except Great Britain is standardization work being carried on upon such a scale or with the intensity found in Germany," concluded Mr. Peck.

Following a meeting of line employes held in the Hydro sub-station at Windsor recently, an energetic organization for the promotion of safety among the workmen was formed. About 50 employes were present at the meeting, which was addressed by G. A. Keuchenmeister, secretary of the Border Cities Safety Council. Mr. Keuchenmeister pointed out that safety work could most efficiently be done by the individual employes, rather than by the employer, and appealed to the men to form habits of safety. Fred D. Hubble, line superintendent of the Hydro, was also a speaker. The men are planning to elect their officers soon, and it is also planned to have Willis McLachlan, secretary of the Electrical Employers' Safety Association, address the new organization during March.

Make a Time Study of Stopping and Starting Your Drilling Machine to Change Tools.

Then Compare the Steady Saving When Using a Jarvis High Speed Tapping Device with Quick Change Chuck.

With the ordinary equipment, the machine must be repeatedly brought to full stop in shifting tools, where there are a number of different operations in a radial drill or heavy duty drilling machine.

ALL THIS LOST TIME IS CONSERVED
BY THE JARVIS TAPPING DEVICES WITH QUICK CHANGE CHUCKS

Engine Cylinder Heads are drilled, tapped and studs set, while other parts are drilled, reamed, counterbored and tapped or spot-faced without a stop.

Jarvis Tapping Devices with Quick Change Chuck can be used on any Radial Drill job that calls for tapping or stud setting. One manufacturer taps a number of different size holes in a wall-radial drill without stopping the machine.

Different style devices fit them particularly for the requirements of the work in hand.

Style S is arranged for heavy work, such as Engine and Motor Castings, Machinery and Automobile Parts

Sometimes a job requires a positive drive with no reverse. Then the Jarvis Style R Device, with Locking Ring, is Used

Any standard Jarvis Product will be sent on trial to Reliable Concerns. Jarvis High Speed Tapping Devices and Quick Change Chucks and Collets are carried solely by the Geometric Tool Company.

PATTERNS

TORONTO PATTERN WORKS, 65 JARVIS Street, Toronto. Patterns in wood and metal for all kinds of machinery. (etfm)

BRANTFORD PATTERN WORKS ARE PREpared to make up patterns of any kind—including marine works—to sketches, blue prints or sample castings. Prompt, efficient service. Bell 'Phone 631; Machine 'Phone 733. Brantford Pattern Works, 49 George St., Brantford, Ont. (ctfm)

AGENCIES WANTED

I WANT TO GET IN TOUCH WITH AN ENergetic young man who is very familiar with the metal-working trade in one of the larger cities in Canada. The work I want him for can be done in spare time—it is not altogether easy, such as "taking candy from a baby," but with little effort he can double his income each week. Apply early to Box 803L, Canadian Machinery.

IF YOU ARE LOOKING FOR A HIGH-GRADE firm to handle through the hardware jobbers and consuming trade throughout the Dominion, write us. It will be worth your while to investigate the special features of our marketing proposition. We know what co-operation means. Write to Box 860T., Canadian Machinery.

BUSINESS CHANCES

WANTED—BY AN ESTABLISHED CONCERN. Twelve to fifteen thousand dollars for a period of from one to three years, to take care of business expansion. This concern will stand the fullest investigation. 8% is offered with ample security to principals only, with an opportunity of becoming permanent associates with the partners, if mutually satisfied. Box 767, Canadian Machinery. (etfm)

REGO WELDING and CUTTING APPARATUS

Oxygen, Acetylene, and a complete line of Welding and Cutting Supplies.

Carter Welding Co.
of Toronto, Limited
7-11 Sheppard St., Toronto, Ont.
Phones: Adelaide 2841 and 1524
(TF)

CASTINGS

BRASS, BRONZE, ALUMINUM
Trolley Wheels, Closet Seat Hinges, Bronze Gears, etc. Jobbing Brass, Bronze and Aluminum Founders.

The Langley & Austin Brass Foundry
GALT, ONTARIO.

CLOSING TIME

Advertisements for this section must be in our composing room Tuesday morning prior to day of issue.

In order that the announcements of your wants, machinery for sale, etc., etc., shall not be delayed, please try to have them in our office with the Tuesday morning mail.

Canadian Machinery

ATTENTION CANADIAN MANUFACTURERS!

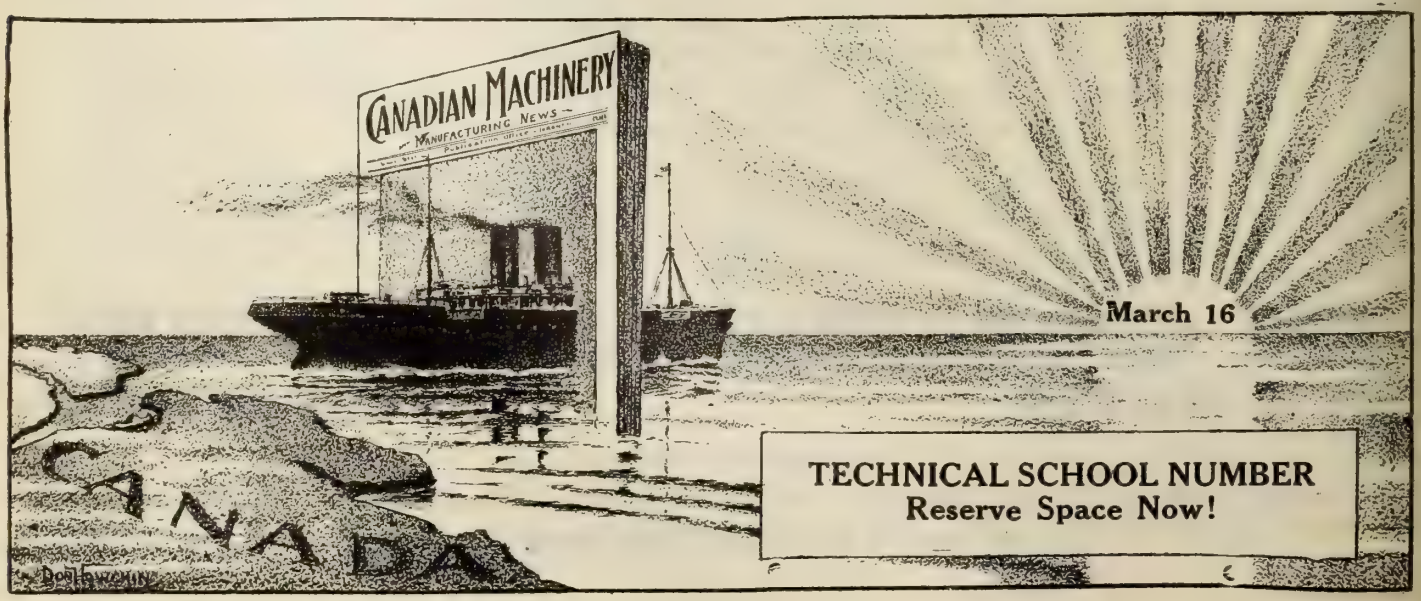
Will license or sell outright basic patents covering a product and process for making same, which is used in practically all mechanisms for power transmission, including automobiles, trucks, tractors, agricultural machinery, machine tools, etc. Is better article and cost is reduced 50% by this process. Ford is using them in cars in the States. A wonderful opportunity to fill up your drop forge plant and machine shop and license others if patents are required. Address: H.N.A. Box 36, Lakewood, Ohio. (C.9M.)
(C 9M.)

FOR SALE

FOR SALE:—ARCWELL ELECTRIC WELDing outfit, Heald Internal Grinder, 10 Pyrometers, Portable Crane, 5 Elevating Trucks, 1 four spindle drill, Sandblast outfit, several tool grinders, Warner Swazey screw machine, 300 feet Matthews' Gravity Conveyor, 3 Tool Furnaces. This equipment almost new will sell cheap. Box 802L.

SITUATIONS WANTED

SITUATION WANTED AS SUPERINTENDENT or general foreman of machine shop, twenty years' experience. At present employed; best of references. Box 861T. Canadian Machinery. (c23m)



MACHINE WORK WANTED

MACHINE WORK WANTED FOR LATHES, shapers, milling machine and planer, etc. Hourly or contract basis. Prompt delivery. W.H. Sumbling Machinery Co., Toronto. (etfm)

EQUIPMENT WANTED

CAFETERIA EQUIPMENT — RANGE, STEAM table, glass shelving, urns, Cash register, etc. Must be in first class condition. Give description and prices. State where may be inspected. Box No. 801L, Canadian Machinery.

WANTED TO BUY—A SECOND HAND LOcomotive crane in first-class condition 7½ or 10 ton capacity. Address Standard Steel Construction Co., Welland, Ontario. (C.9.M.)

In the February 16th issue of "CANADIAN MACHINERY" we listed over 300 machines of different types. We have been successful in disposing of many of these tools. We still have many left.

Turn to that issue. See pages 52-53. Pick out the machine you need. You will find it there. Then get in touch with us immediately.

All to go in 60 days—First come, first served.

163 Dufferin Street

Montreal TORONTO Winnipeg

Technical Men!

With the co-operation of the Departments of Education of the various Provinces, and with the assistance of principals and instructors, we purpose publishing on March 16th a number that will be a perfect mine of information in the development of Technical Schools to date. There will be such an exchange of ideas, such a volume of practical information, that the number will be regarded as a text book and will be preserved indefinitely for reference purposes.

Articles are appearing in CANADIAN MACHINERY every week, that are just what you have been looking for and for a long time. If you want to know what kind of articles these are—write us for a pamphlet explaining fully.

Subscription rates are $4.00 in Canada and $4.50 in the United States.

Sit right down now and fill out this form and send it to us—with your remittance attached. **You won't regret it.**

CANADIAN MACHINERY,
143-153 University Ave.,
Toronto, Canada.

Please enter my subscription to CANADIAN MACHINERY for one year—52 issues. I enclose herewith $4.$\frac{00}{100}$ which is the rate for one year.

25% More Circulation
—*No Increase in Rates!*

BY UNDERTAKING to fill, for their unexpired terms, all paid-up subscriptions to FARMERS' MAGAZINE—which ceased publication with its issue of February 2nd—MACLEAN'S MAGAZINE has thus added to its list at one stroke, approximately 20,000 paid-in-advance subscribers.

Through the general use of the automobile, the farmer has become to-day practically a suburbanite. Canadian farmers of the class who have been subscribing to FARMERS' MAGAZINE are in a position to buy automobiles, pianos, phonographs, and all other articles or conveniences that make for comfort and a higher standard of living.

Besides being consumers of the best grades of merchandise, they are to-day taking the keenest interest in politics and all public and economic questions.

FARMERS' MAGAZINE and MACLEAN'S MAGAZINE have been the outstanding mediums in Canada, serving separately the rural and urban fields. The decision to discontinue FARMERS' MAGAZINE and to fill the subscriptions with MACLEAN'S, is the result of the maturity of a conviction that the subscribers to our farm magazine are ready now to demand and appreciate a general national magazine like MACLEAN'S in order to have the information and entertainment which they desire — a magazine that will furnish them with good fiction, political articles and Canadian national news of a character not found in the farm papers or newspapers. No change is being made in the physical make-up of MACLEAN'S MAGAZINE, or in the character of its editorial contents.

95,000 Gross Circulation
Rate Based on 70,000 A.B.C.

The addition of FARMERS' MAGAZINE subscription list to MACLEAN'S circulation, after all arrears and duplications are eliminated, commencing with February 15th issue, gives MACLEAN'S MAGAZINE at once a total circulation of more than Ninety-Five Thousand copies each issue.
This gives a big general covering of town and city circulation, plus a highly selected farm circulation. It provides the tremendous influence of the "leadership" families in every city, town and village right across the Dominion, together with the most prosperous and progressive farmers in each trading territory; and constitutes a service which is not equalled or even approximated by any other general publication in Canada.

95,000 National magazine circulation in Canada, on a per capita basis, is equal to at least 1,500,000 in the United States.

**MACLEAN'S is the outstanding,
big, covering medium in Canada.**

THE LINE RATE, FOR THE PRESENT, REMAINS AT 70 CENTS

First and Fifteenth of Every Month

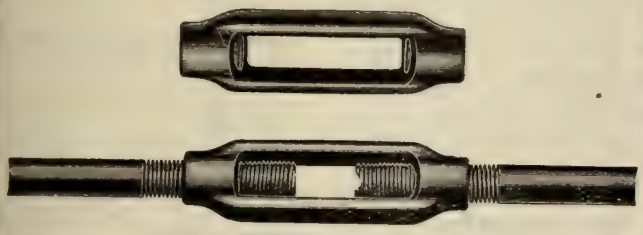
Prepare for Prosperity



Look your plant over from cellar to roof—or better still, let REED Engineers do it for you. Perhaps you need new floors—a conveyor system—"Almetl" Firedoors—an Exhaust System or repairs to your roof. Our Engineers will only recommend that which is essential to put your plant into most efficient state to meet the coming prosperity.

Write or phone us to-day.

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

KEMPSMITH

NO. 2 PLAIN MAXIMILLER

Kempsmith Millers are built in three sizes each in the Plain and Universal Cone Types, two sizes of Maximiller Geared Head Types, a Production Type, with a choice of three table ranges, and two sizes of Vertical Geared Head Type. Our Knee Type Millers can be fitted with a complete line of attachments, which greatly increase the range of the milling machine.

Literature will be gladly sent upon request.

Laboratory Accuracy at a Toolroom Price

A TRIAL of Hoke Gages under your own conditions will convince you that our claims for these blocks are justified. You take no risk—the Pratt & Whitney guarantee is broad enough to assure satisfaction. The price permits the use of Hoke Blocks in everyday toolroom work. A reference set laid away in the safe is not earning for you what it should.

Using a stack of Hoke Gages for checking profile on a Maag Gear Cutter.

The Story of Hoke Gages—
A Booklet that will Interest You

THIS interesting catalogue will be sent on request to Manufacturers, Superintendents, Engineers, Inspectors, Tool or Production Foremen, and others who want to KNOW. It contains information covering — Gage Blocks, Registered and Identified; Means of Identification; Guaranteed Reliability; Advantages of Square Design; Reason for the "Hole"; Various Combination Sets; Attachments and How to Use Them; Some Everyday Applications—Testing Tapers, Scribing Lay-outs, Checking Profiles, etc.; Toolmaker's Flats; Mikechecks; Swedish Type Gages.

Details, prices—all the information you want—Are yours for the asking.

P & W

Pratt & Whitney Taps

"With the 'Con-eccentric' Land"

P & W Taps are **Good** taps—easily the best where accuracy and high speed are essential. They cost more to buy, but less to use than others.

If you're doing work that calls for big production and for unusual precision, give them a trial. You'll be back for more when you see them prove themselves.

The "con-eccentric" land — the special feature of Pratt & Whitney Taps, permits sharpening on face of the cutting edge without affecting size. It lengthens life and assures accuracy hitherto thought impossible in a commercial tool.

DEPENDABLE POWER EQUIPMENT

SHOWING A G. & McC. 2-CYLINDER COMPOUND ENGINE DIRECT CONNECTED TO A 250 K.W. ELECTRIC GENERATOR

At The Central Technical School, Toronto

An engine similar in type to the above is being installed in the new Technical School in the course of erection at Windsor, Ont. It is a 2-cylinder compound, 11″ and 17″ x 8″, 500 R.P.M., direct connected to a 90 K.V.A. 220 Volt generator. The Montreal Technical School has a G. & McC. installation consisting of a simple, heavy-duty Goldie Corliss Engine, 11″ x 30″, direct connected to a 90 K.W. generator, 150 revolutions per minute. At the Toronto University a G. & McC. installation consists of a three quarter million-gallon Rees RoTurbo Pump.

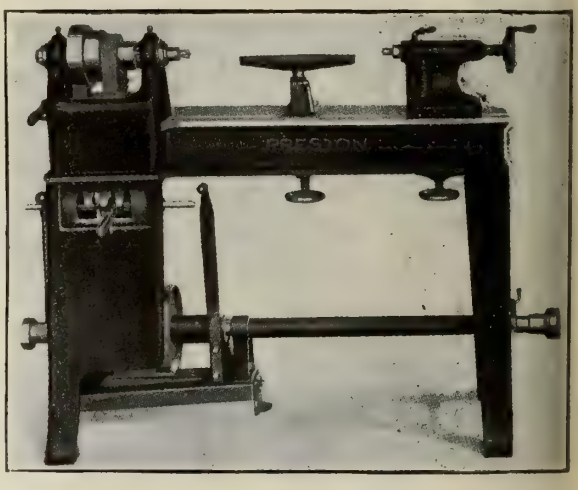
A battery of 12 "Preston" Woodworking Lathes as installed at the Central Technical School, Toronto

PRES



Preston Woodworking Equipment is recognized as the proper equipment for Technical Schools of Canada. This is evidenced by the fact that Preston Equipment is installed in the Technical Schools of Toronto, Hamilton, Ottawa, Niagara Falls, Windsor, Chatham, Woodstock, Sudbury, Fort William, Prince Rupert, B. C., Chilliwac, B. C., and London, Ont. The Institute for the Blind at Belleville and different Soldiers' Civil Re-establishment Schools are also users of Preston Equipment. Note the illustrations on these two pages, showing Technical School Installations.

These machines are standard equipment for technical schools and have been installed in these institutions all over Canada.

To appreciate better the superior construction of these machines you should send for complete description.

HENDEY

Gives Excellent Tool Room Service

Hendey Crank Shapers and Hendey Lathes are of great value for general tool room service. The adaptability of both machines is truly remarkable.

This installation, in the plant of the Waterbury Buckle Company gives an excellent idea of the convenience of the Hendey 20-in. Crank Shaft. The machine is planing off the bottom of a cast iron die bed.

Bear the reputation of the Hendey in mind when considering additional shapers or lathes.

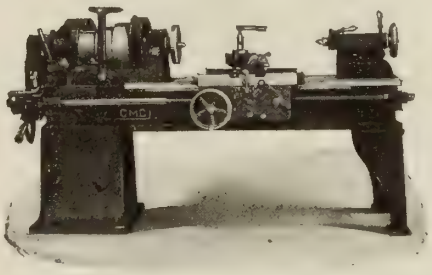
Ideal Technical School

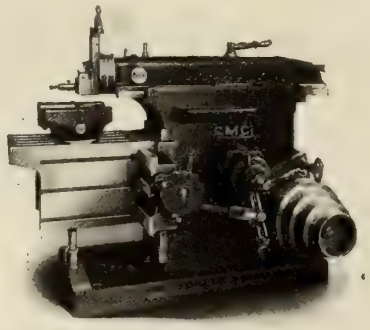
C.M.C. MACHINE TOOLS and



Start the student on C.M.C. Manual Training Machines. Up to date tools will help to make him a fine workman, and when he graduates, he will find more of them in operation than any other make. They are good to learn on and good to work on.

14″ x 6′ Toolroom Lathe
(Quick Change)

14 inch Tool Room Lathe



This is the Lathe that was originally designed and built for one Technical School which installed sixteen of them. It is very compact but is capable of a great variety of work. Notice the "back gears" are placed in front of the headstock.

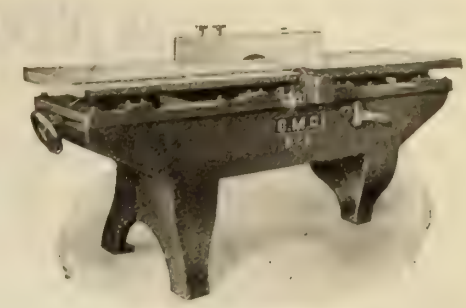
16″ x 6′ Quick Change Gear
Engine Lathe

Engine Lathes—*Quick Change*

Accuracy, strength and convenience are outstanding features of this Lathe. Changes of belt or gears are within the operator's reach, and a special belt shifter safeguards the Student from danger in shifting the belt.

20″ x 22″ Crank Shaper

20 inch Crank Shaper



A tool especially adapted for Technical Instruction. The operator can change the length of the stroke, the position of the ram, the cutting speed, the rate and direction of the feed, and operate the down feed to head without moving from his position or stopping the machine, and without endangering himself in any way.

The Load You Can't Estimate

NO matter how great is the foresight of the machine designer, he cannot guard against unexpected thrust loads on the bearings caused by conditions beyond his control.

The Deep Groove Bearing can withstand thrust loads greatly in excess of its radial capacity and coming from either direction.

Both the design and quality of this double purpose bearing are endorsed by the mark **SKF** and are backed by the world-wide researches and long experience **SKF** Industries.

This experience is at your disposal and you are urged to submit your bearing problems to us for free and impartial advice.

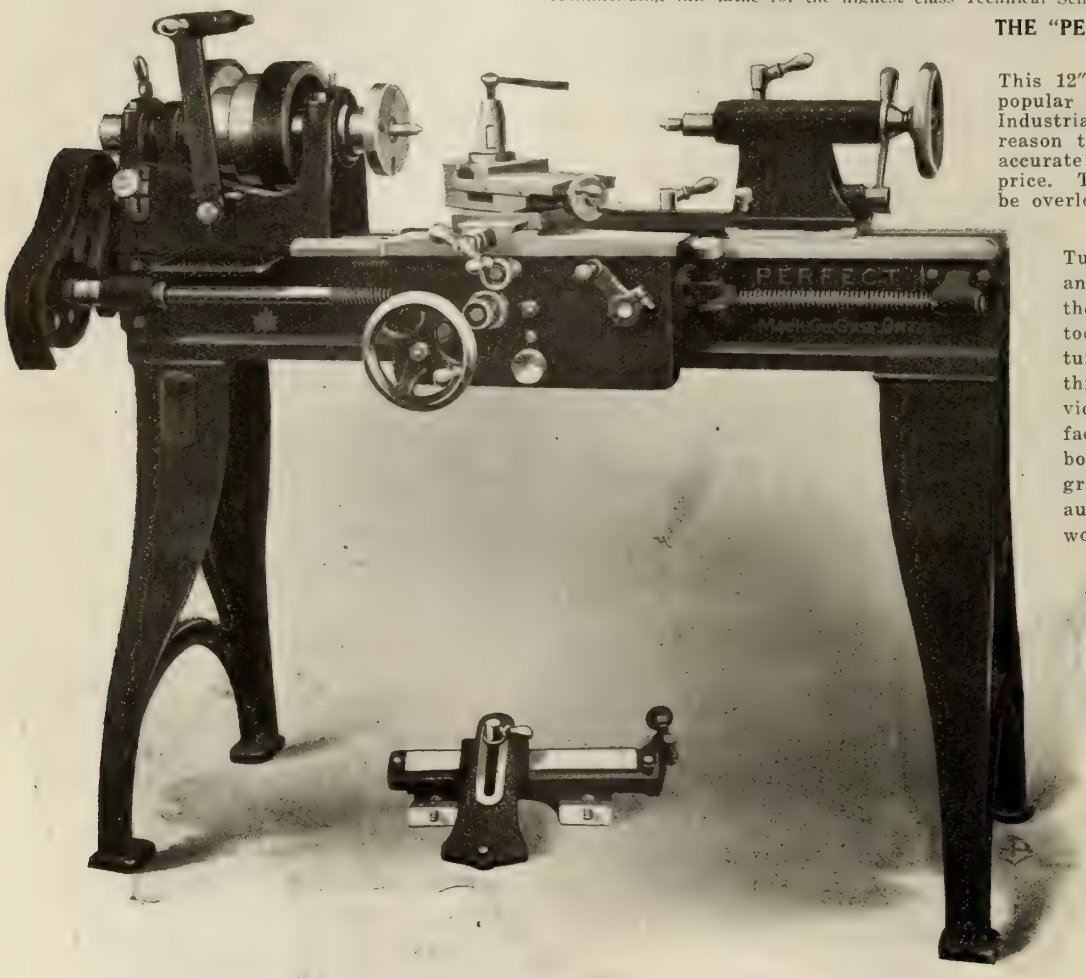
Use Starrett Tools



"Perfect" Lathes Make Perfect Schools

The "Perfect" Little Bench Lathe--The Most Useful Tool in the Technical School.

It is an accurate producer of an unusually wide range of work yet easy to operate and small power consuming. With 8-inch swing, 13 inches between bed it has every improvement found on a large Tool Room Lathe. The handy size and great adaptability prove an ideal means of high class instruction.

A simply designed headstock; high carbon steel spindle; carefully cut lead screw; properly built carriage and screw cutting range from 3 to 144 per inch are features recommending this lathe for the highest class Technical School work.

THE "PERFECT" TECHNICAL SCHOOL LATHE

This 12" x 4'6" lathe has proven a popular choice with Technical and Industrial Schools for the simple reason that it combines high-grade, accurate work with very moderate price. This is a point that cannot be overlooked.

Turning out work on a quality and quantity footing with the more expensive lathes this tool has many valuable features. A good range of threads and feeds, spindle providing for actual centering of face plate; belt shifters on both heads and countershaft; graduated countershaft and automatic carriage stop are worthy of note.

When in need of Hack Saw Machines, High Speed or otherwise, Drilling Machines, Grinding Machines, Bench or Machine Vises, Dumping Grate Bars, Stokers, Grey Iron Castings or special machine work of any kind let us talk to you.

For Every Requirement

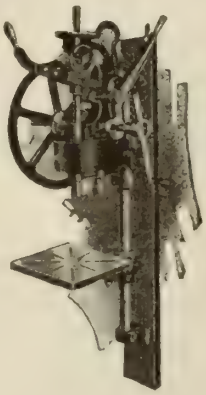
"Canadian" Forges

The No. 90-D Stationary Down Draft Forge shown here is one of the most approved models for technical school use. The hearth is large and deep—made of cast iron. A deep, round cast iron tuyere bowl is provided with clinker breaking blast valve. Each forge has a blast gate, coal box and water tank as shown. The blast gate is operated by a lever at the side of the forge.

The down draft principle used on this forge is the most approved type and is in use all over America. We have a complete line of forges for all requirements with various types of blowers. Send for our catalog 108-16.

"Canadian" Drills

HAND AND POWER—ANY SIZE



We illustrate the Canadian 10-inch Junior Drill, with two speeds, and the No. 421. We make many other drills.

"CANADIAN" DRILLS
HAND AND POWER—ANY SIZE

Technical schools all over the country are users of Canadian drills. We have a type for every service. The 10-inch Junior shown here is a small bench drill; has two speeds, lever feed, tight and loose pulleys. It will do accurate work, drilling ⅜-inch holes to center of 10-inch circle.

The No. 418 is a good substantial post drill, with a capacity of 1½ inch holes to the center of an 18-inch circle.

Write for the catalog which illustrates our complete line of drills—210-16.

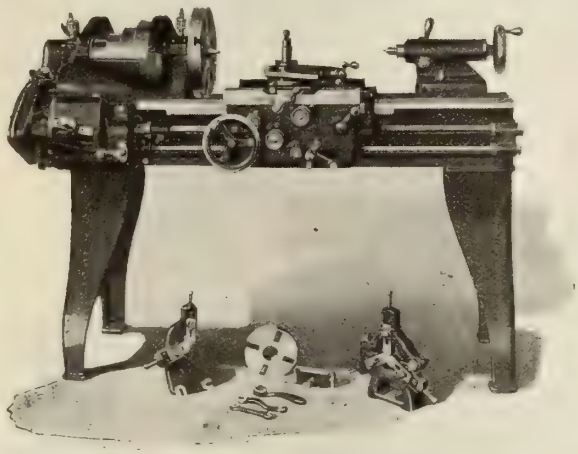
The Best in Taps

Dies & Thread Cutting Tools

Is None too Good for

Technical School Students



True—they are only students now. Almost any kind of tool would seem good enough to experiment with. But is it? Watch these same students tomorrow as they step out to fill important places in Canadian industry. Superintendents, Shop Foremen, Engineers, Executives. They must know all about good tools, **then—NOW** is the time to teach them.

Preston & Schwartz Tools are made by Tap and Die **Specialists.** We make nothing but Cutting Tools. All are unconditionally guaranteed. A trial order will prove their superior merits.

Preston & Schwartz Limited

Galt, Ontario, Canada

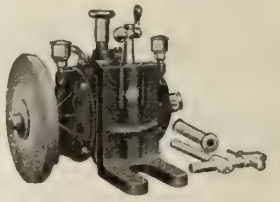
Rockford "Economy"

(13 INCH SWING)

Quick Change and Safety Feature Adapt it to Technical Schools

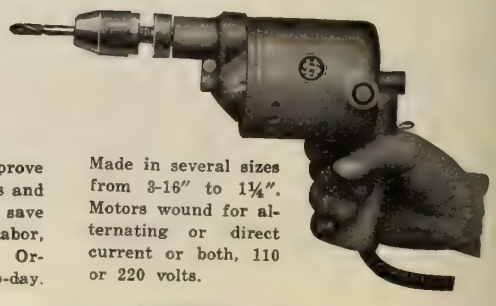
A small heavy duty machine capable of **big** production. All gears are completely covered safeguarding operator against injury. Cut steel gears.

32 changes of thread may be obtained without reversing. Lead screw used only for thread chasing. **Write for circular.**



ROCKFORD LATHE & DRILL CO.,

ROCKFORD, ILL., U.S.A.



U. S. ELECTRIC

Drills and Grinders

Can be Attached to any Lamp Socket

For drilling in metal these drills are the superior of every other kind of portable drill. Their operating cost is only half that of air drills. And they can be attached to any lamp socket.

A trial will prove that our drills and grinders will save you time, labor, and expense. Order a few to-day.

Made in several sizes from 3-16" to 1¼". Motors wound for alternating or direct current or both, 110 or 220 volts.

Good Lubrication Demands Efficient Oil Storage

No matter how good the oil you buy, you cannot have correct lubrication unless it is stored and handled properly. Gritty oil means added friction on machinery parts, with a resultant rapid depreciation.

Bowser oil batteries will show *you* the way to efficient, economical and safe storage and handling of your oils. The leak-proof Tanks keep out all grit and dirt. The Piston-Type Measuring Pumps deliver the oil quickly and accurately. Bowser takes a minimum of floor space and centralizes your oil storage.

Let us prove what Bowser will do in *your* shop.

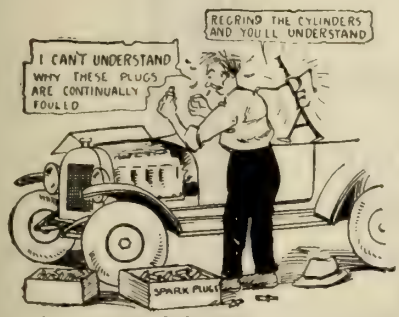
THE NIGHTMARE OF EVERY MOTOR OWNER

Excessive use of gas and oil

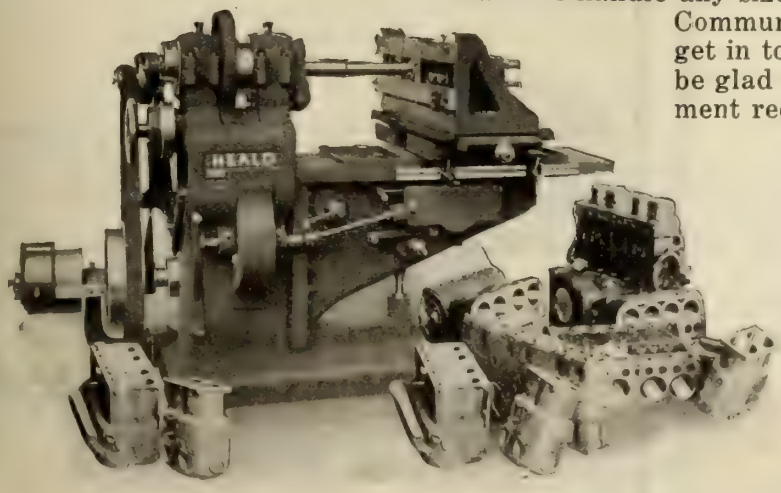
If You Could Cure These Troubles



What a business you would have

Lack of power and pep

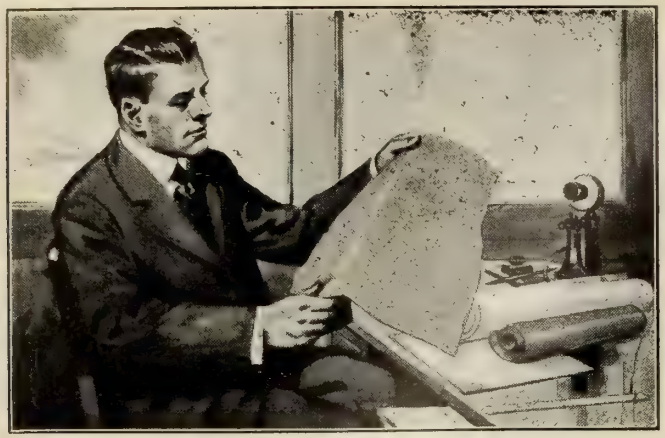
IT requires no great mathematician to figure out the business that is available for any machine shop, auto repair shop or garage that can cure the everyday motor troubles such as lack of power, excessive use of gas and oil, sooty spark plugs, skipping, etc.



This IS being successfully done by HEALD owners in various parts of the country to-day by regrinding the cylinders and fitting new pistons and rings. In some localities it is well taken care of but there are still many central points where some live, up-to-date fellow is going to make good. This is particularly true at the present time for the economy of reground cylinders appeals to the owner of both the low and high priced car.

Carbon and dirty spark plugs

If you are running a shop, consider these facts and then see if there is anyone in your neighborhood who will take care of this work. If there is and you are not in a position to put in equipment, send your work to him and get your commission. If, however, you find no one with a Heald equipment in your trading center, it is a business opportunity you cannot pass up. Regrinding is high grade work, commands high prices, and this Spring will be the high peak in the business.



The Heald Style No. 55 is built especially for cylinder regrinding shops, simple, reasonably priced and with a range that will handle any size or style of block that may come in. Communicate with the home office direct or get in touch with any of our agents who will be glad to go over the possibilities and equipment required.

Unrivalled Facilities for Success in Mechanical Engineering and more than 300 other vocations.

No field of opportunity offers greater scope than that of Mechanical Engineering and no other educational institution has trained so many splendid successes in it as the International Correspondence Schools. The spare-time home-study method of learning is wonderfully suitable for the young mechanic who must continue to earn while he learns to earn more.

In 30 years many thousands of Canadians have profited from the training of this Institution, which created the method of teaching by correspondence and has procured unrivalled texts for home-instruction. These texts are formed into more than 300 Courses, each EASY TO STUDY, EASY TO REMEMBER, AND EASY TO APPLY and supplemented by a highly qualified faculty that give personal attention to every student throughout his progress to knowledge and efficiency.

Thus the I.C.S. provide YOU with the best and most convenient opportunity of self-advancement you can find anywhere. Let us help you in Mechanical Engineering or any other vocation you prefer. We can give you the training you need right at home in your spare time, so make your start without another hour's delay. As a first step, mark the coupon and mail it to Montreal. You'll receive a most interesting booklet in return.

Alundum 

Crystolon

NORTON GRINDING WHEELS FOR MALLEABLE IRON CASTINGS

Malleable Iron Castings, such as are used for agricultural implements and so forth, are ground to remove gates, fins, seams, and surface bubbles. Some manufacturers have found it more economical to grind these castings before annealing. Others grind them when soft or after annealing.

The wheel to give maximum service and most rapid production should be composed of:

1. An abrasive with physical properties especially adapted for **cutting** malleable iron. (The same abrasive should not be used for unannealed and annealed iron).
2. Abrasive, grain size, and grade or hardness of wheel selected to give maximum production per hour and maximum production during the life of the wheel.

To satisfy all of these conditions, use Norton Alundum Vitrified wheels for annealed malleable iron castings, and Norton Crystolon Vitrified wheels for unannealed malleable iron castings. The grain and grade of the wheel will be determined by the type of castings you have, dimensions of the wheel, and your machine equipment.

Write for further particulars.

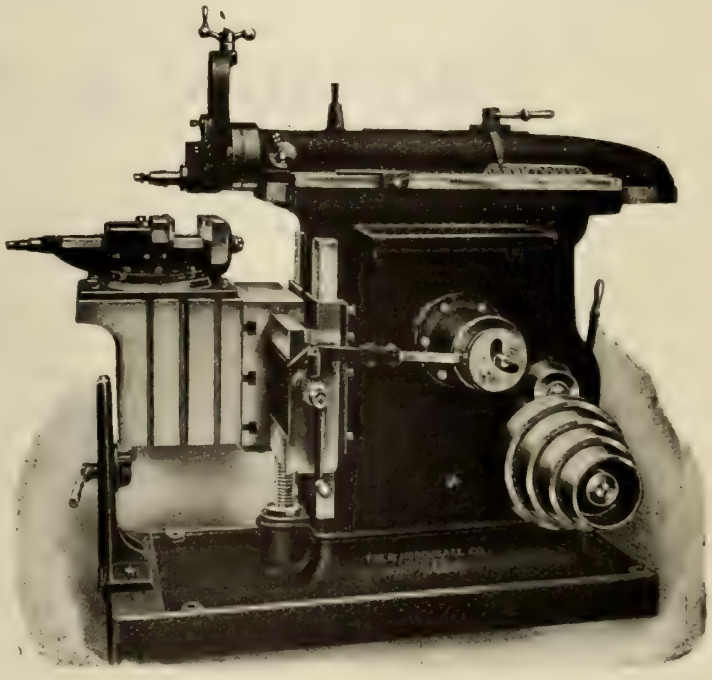
McDOUGALL

Ideal Tools for Technical Schools



Heavy cast iron back gears and steel pinions as shown in above cut are amply protected by shades or guards

Machine tools for technical school use should embody the most advanced principles of construction—they should be finely built and finely finished. Such are the qualities seen in McDougall Drills and Shapers.

Improved 20-inch Drill

It possesses a valuable feature for technical school purposes in being a machine for all round work. It will drill 1¼-inch holes in steel and 1½-inch holes in cast iron from solid metal, and will bore up to several inches in cored holes. Equipped with back gears, power feed, automatic stop and quick return. Only best material and best workmanship is used in the construction of this tool.

16-20-24-inch Shapers

Students are instructed in the best modern practice when machine tools of this class are used in technical schools. McDougall Shapers are sturdy, simple and convenient. The columns of the machines are massive and well-braced. Ample opening is given under ram for keyseating and other like work. These ideal shapers have many other distinguishing features. Shall we mail complete description?

CANADIAN MACHINERY
AND
MANUFACTURING NEWS

VOL. XXVII, No. 11 MARCH 16, 1922

As the Twig is Bent, The Tree's Inclined

"WHAT SHALL we make of our boy?" is a question thousands of parents ask themselves every year, but few probably realize the enormous responsibility they are taking in arriving at a decision.

The actual choice of a trade or profession is a matter of prime importance, but once this question has been decided, the selection of a method of training is one of equal moment.

The wonderful work which technical schools are doing for the youth of Canada is not fully appreciated. Parents seldom take enough interest in it to visit the schools and see for themselves the work which is entailed in the training of their children.

A technical school in a city of any size to-day is a small city in itself, for there you will find classes in practically every industry. True, the work may not be as intricate as that being completed in the outside world, "but Rome was not built in a day."

The twig is being bent in the right direction and with good results, and later in life these twigs will become trees and will grow up strong in knowledge and well able to fight any industrial storms which may arise.

To those directors of technical education, and principals of the various schools who have helped us prepare this special number we offer our best wishes for future achievements. Let them decide to co-operate with each other, for in union there is strength. Get together occassionally and frankly discuss your various problems. Do not hoard up a good idea. Give it freely, realizing that the very idea you are giving may later bring you back a better one. Above all see that the method of tuition in your schools is as practical as possible.

Keep in mind the fact that after the boys in your establishment leave to take up their work in the various factories it will be results that count. Give the boy a good start by supplying him with as much production work as possible. Get the fundamental principles and methods of operation of the various machine tools thoroughly ingrained into the students' mind, then show him how manufacturing plants would produce different types of work. Do not be content with exercises. Boys will take a deeper interest in work which they know is of practical value, and not merely a piece which when completed is thrown away or stored for exhibition.

Manufacturers are taking a deep interest in technical education, and their viewpoint should be asked for and carefully considered. They can give instructors the benefit of their manufacturing experience and can often suggest to them some part which could be used as a sample for tuition, and which would employ a variety of machining operations.

Some schools make a practice of being self supporting as far as possible making work for outside firms. This is a splendid move and should be encouraged.

Visits should be arranged occasionally whereby students could be taken through the larger manufacturing plants, having the various operations explained to them by competent guides. Some schools are at present following this practice with good results, but the chief value of such a visit rests with the capability of the guide and his powers of quick and accurate explanation. Ideas will be obtained on visits of this character which will have far-reaching results.

The development and growth in technical education during the past few years has been marvellous, but it should be nothing in comparison with the expansion during the next few years. At present many municipalities are contemplating the erection of new schools, and it is to be hoped that when these are completed the courses adopted will be as modern as the building. "Keep up with the times" might well be a good slogan for principals of the various technical schools, and this motto should be carried out to the placing of only the best of equipment for the students' use.

It is questionable if we will reach the point where a standardized course is possible, for local conditions may necessitate a certain variation in practice, but as near as possible, certain fundamentals should be included in every course of a mechanical nature in the province. Get the manufacturers in your locality interested. Induce them to come down and see what you are doing. Ask for their co-operation. Make them feel it is their school as well as yours, then you will be on the royal road to success.

When bending the twig, see that it is bent in the right direction. Do not let a boy study the engineering trade if you feel his time will be wasted in that field. Place him where he will make the greatest success.

Education of Youth Is Most Essential

Necessity of Vocational Training Has Always Existed—Those Entering Industrial, Commercial or Agricultural Fields Have Equal Rights With Those Preparing for Professional Callings—Needs Vary With Conditions

By DR. F. W. MERCHANT
Director of Industrial and Technical Education in Ontario

WE ARE hearing a great deal about fads and frills in education. New subjects of study and new methods of instruction and organization are usually characterized and often condemned by these terms, but in discussing the vocational education of the youth, one cannot be accused of advocating the new or faddish, because, without doubt, this type of training is the oldest of all forms of education.

Education had its origin when primitive man began to store up his experiences and to utilize them for the guidance of the youth. These experiences grew out of his primitive needs for food, clothing, shelter, and defence. Accordingly, in the beginning, instruction was concerned with subjects that were purely vocational in character.

The necessity for training the youth in the vocations by which they are to serve society and to earn their living is not to be argued. The need for such training has always existed, and, in one form or another, provision has always been made for it, although changes have taken place from time to time in agencies and in methods.

The simple occupations of primitive man were taught the youth by their parents. With certain occupations, as for example, of the household and of the farm, this practice remains, in a measure, with us until the present time.

A Specialized Service

In commerce and in trades and industries, vocational instruction passed from the parent and the home, to the employer and the counting house or the workshop. Thus there was built up an elaborate system of apprenticeship which involved a great variety of callings. This system, in its time, proved to be a most effective means of vocational training. It reached its highest stage of efficiency in the training for handicrafts under the Guilds. Apprenticeship remained in more or less effective operation until the end of the last century. But with higher specialization in the processes of manufacture and with the organization of larger industries on a basis for economic quantitive production, the apprentice system has broken down in our day, and we find ourselves now in a period of reconstruction which has created a demand for making vocational training a specialized service.

The need for such a service has led many industrial establishments to set aside accommodations and to provide equipment and instructors for the training of employees. But the present tendency is to demand that schools be established as a part of the national system of education. This demand comes both from the heads of industries and from the workers. The Educational Committee of the American Federation of Labor puts the case thus: "We believe that the education of workers in trade or industry is a public necessity, and that it should not be a private but a public function, conducted by the public, and with the expense involved at public cost."

Recognizing a Principle

Governments are beginning to accept this responsibility for the vocational training of the youth and to establish schools. Our own Provincial Government long ago acknowledged the obligation when it gave support to professional schools of medicine, law, engineering, and pedagogy. In now promoting a wider range of vocational schools it is but recognizing the principle that those who are to enter industrial, commercial, or agricultural fields or to work in the home have equal rights with those who are preparing for the professional callings to vocational training at public expense.

The Vocational Education Act of 1921 which replaced the Industrial Education Act under which vocational schools were previously operated, provides for the establishment and development of vocational schools of a variety of types for instruction in a wide range of courses in industrial, technical, home-making, art, commercial, and agricultural subjects.

Certain fundamental principles underlie the provisions made by the Department of Education for the organization of schools under this Act:

First, vocational instruction is to be based on a thorough training in the essentials of a general education. Not only is such an education necessary as a basis for citizenship, but a survey of the needs of industries has shown that lack of a general education is as frequently the cause of the failure of a worker to secure advancement as the lack of specialized knowledge or skill. To secure for every citizen the advantages of such an education, the age of compulsory attendance at school has been raised by the Adolescent School Attendance Act from fourteen to sixteen years.

Second, a Provincial system of secondary education in addition to providing adequately for a complete and flexible system of general high school training must make provision for the organization of schools designed to give boys and girls looking forward directly to employment a thorough training in the essentials of a general education and, at the same time, to furnish a special training in the subjects and operations which are fundamental to the occupations in which they expect to become employed. Our full-time day organized in response to a very general demand for more practical types of secondary schools to prepare young people who are not to enter professional life for a career in the home, in agriculture, commerce, or industry.

Third, while the training in the direct practical requirements of some vocations can, in a fair measure, be provided for through school instruction, yet in many occupations, especially of an industrial character, this training should be accompanied or supplemented by instruction under working conditions. The provisions for part-time day schools and for evening schools, therefore, are made an essential part of the organization of vocational education. To carry out satisfactorily plans for such schemes, the apprenticeship system in some form should be restored and schools and industrial establishments should co-operate in the complete training of apprentices.

The function of the school should be to give instruction in the related knowledge and the operations fundamental to an industry, while the apprentice perfects his skill and develops his industrial intelligence at work in industrial establishments under productive conditions. The provisions for part-time instruction under the Adolescent School Attendance Act facilitate the carrying out of schemes of instruction on this basis.

Needs Vary With Conditions

The courses on the practical side to be provided for in any school depend upon the particular requirements of the centre in which the school is established. Needs vary with the conditions in different localities. It is clear that the practical work in a vocational school in a centre where mining is the only industry and where a large percentage of the young people who leave school engage in it, should be different from that provided in the school of a large city where the graduates of the school find employment in a great variety of commercial and industrial establishments. The board in charge of a school in any municipality is expected to make a careful survey of the occupations of the district with a view of determining the character of the practical instruction which should be provided to meet the needs of the community.

(Continued on page 49)

This School Shows Remarkable Progress

Over 10,000 Pupils Enrolled—Large Pipe Organ Installed as Direct Effort of Teachers and Students—Special Facilities for Thorough Instruction—Orderliness an Outstanding Feature

TECHNICAL education in the city of Toronto dates back to 1891 when evening classes were first organized and instruction carried on in the old Wycliffe Hall. It was not long, however, until the increased demands for tuition necessitated additional class accommodation, so that in 1900 another building was acquired with the intention of starting day classes, these being inaugurated in the following year. Reorganization was necessary in 1904, when under the new Board of Education the school's name was changed to that of the Technical High School. The need for increasing facilities to provide for the rapidly growing demand for technical education was so evident that plans were laid in 1911 for the erection of a building that would meet all the requirements of the city in this respect. The school was completed in 1915 and the present enrollment shows that nearly 3,000 day pupils and over 8,000 evening students are attending the various classes, about 80 per cent. being enrolled at the Central school. The remainder distributed between the other three branches, Humberside, Oakwood and Riverdale.

Building Features

The building, which faces west of Lippincott Street, is 430 ft. long and 227 feet deep, four storeys in height and occupies two city blocks. The floors are designated A, B, C, D; A being the basement floor, where all the heavy mechanical equipment and shops are located; B the main entrance floor and general offices; C floor is devoted to women's work in domestic science and art, and the boy's lunch room. The top floor is set apart for science, chemistry and drawing class rooms. In the tower of the building, a room is provided for life studies in art.

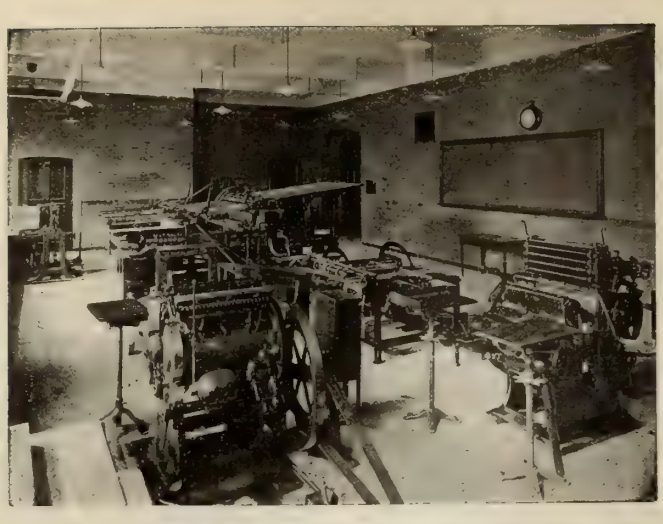
The Auditorium

One of the most imposing places in the building is the large auditorium, 80 ft. by 90 ft., consisting of main floor and gallery, with seating capacity for almost 1,300 persons. Brief opening exercises are conducted every morning for a period of about ten minutes. It is indeed an agreeable sight to see about 1,300 students and teachers gather together for short devotional service (non-denominational in character) before taking up the work of the day. It will be interesting to mention that only last year an organ costing $14,000 was installed as a memorial to the teachers, pupils and graduates killed in the late war. The fund for this purpose was raised entirely by the pupils and teachers through bazaars and concerts held in the school building. The school has a first-class orchestra composed of boys between he ages of 14 and 20.

The industrial course for boys and young men extends over a period of four years, and is designed to prepare them for the pursuits of industrial and commercial life. During the first two years of a course no attempt is made to have a boy specialize in any particular line of work, but a thorough grounding of the fundamental principles of associated trades is given the boys so that they are better able to make the proper decision when the time comes. Many a young man's career has been hampered owing to the fact that he has been forced into a trade that he is not mentally fitted for. The varied nature of the industrial courses in the technical school make it reasonably possible for a boy to "find himself" before he has committed his future to a trade or profession that will not show him the proper return for time and effort expended. While the instructors are ever ready to assist a boy in making a choice, it is seldom found necessary as the latent faculties are given ample scope long before his course is completed. If a boy expresses a marked desire to continue his studies along specific lines then instruction is given with that end in view, concentrating on the different subjects that are allied to the goal of the boy's ambition.

The subjects covered by the industrial course include mathematics, physics, chemistry, mechanical drawing, free-hand sketching, shop work, English, drill, gymnastic and swimming exercises; these studies being suplemented in the last year by such subjects as geology, mineralogy, steam engine and power plant, architecture and building construction, estimating, clay modelling, printing in all branches, practical painting and decorating, metallurgy and assaying, and electro chemistry. Every needed facility is provided in engineering and chemistry courses for a comprehensive study of these subjects.

Thirty standard class rooms are provided and these are so arranged that a minimum loss of time takes place in going from a laboratory to a lecture room when taking up practical and theoretical studies of the same subjects. Lockers and cloak rooms are provided for each individual class room. These were installed by the Dennis Wire and Iron Works Co.



Wood Working Shops

The purpose of the different departments of technical school work, especially the day courses, is not that the boys will become experts in any particular line of activity but rather to make him familiar with the general features of construction and methods of proced-

This article is compiled from information obtained through the courtesy of A. C. McKay, B.A., L.L.D., principal of The Technical Schools, Toronto, and his staff.

Section of foundry

Partial view of printing department

ure in various industrial pursuits. There are seven rooms devoted to instruction in wood-working, viz., two elementary shops, two pattern shops, one cabinet shop, one carpentry shop and one mill room. All of these shops are equipped with modern machinery and material for every class of wood work. Individual instruction is given each boy and in the elementary classes the same work is performed by every boy so that one often benefits by the work of another. In all cases the pieces are made from drawings previously made by the student in the drawing class room.

For advanced pupils a large construction room 80 x 37 x 30 ft., provides ample space for the erection of two fair sized dwelling houses. Instruction is given in framing, roof trussing, cutting in doors and windows, erecting staircases, plastering, wiring, plumbing, paperhanging, and other work, so that boys are enabled to test out their ability to carry out the work of the different trades involved.

Forge Shop

Ample provision is made for the study of forge work and heat treatment as it bears on the associated studies of the industrial courses. Twenty individual "Buffalo" down draft forges are installed, together with a gas heating forge and hardening furnace. Heat treatment control being taken care of by a complete Bristol pyrometer installation. Boys are given a thorough training in the characteristics of various steels, method of heating and forging tools for machine shop, welding, effects of hammering steel at different temperatures, hardening and tempering, annealing, etc., and other details pertaining to this department. A power hammer and hand shearing machine minimizes the physical efforts of forge work so that the boy's time is fully occupied in learning the more essential features of forge operations. Parts are made from previously prepared drawings.

The Foundry

The foundry is a well-lighted room 50 ft. x 30 ft., and contains a one-ton cupola, three brass furnaces, one core oven, a pneumatic rammer, swivel moulding machines, iron flasks and small tools. Class and individual instruction is given by an experienced foundryman. The elementary work consists of the preparation of simple moulds and cores, the study of the materials used, such as sands, binders, etc. Molten lead is generally used in making the simple castings for the beginners' classes, and more intricate work is covered as the studies progress, and the use of the moulding machine and cupola charging are gradually introduced to the work. Brass casting and preparation of non-ferrous alloys are part of the regular work at later stages.

Machine Shop

The large machine shop is 57 ft. x 57 ft., located on the basement floor, and in the center of the building so that the glass roof of the court provided ample light and air. Artificial light is furnished by semi-indirect nitro-tungsten lamps. Five motor-driven tool-room lathes are installed. These tools were supplied by Reed-Prentice Co., Flather & Co., Lodge & Shipley Machine Tool Co., R. K. LeBlond Machine Tool Co., and W. P. Davis Machine Co. General engine lathe instruction work is given on sixteen 14 in. Canada Machinery Corporation machines. Milling machine equipment consists of a motor-driven No. 2 Cincinnati plain miller, one No. 1½ Brown & Sharpe plain miller, and two small universal Hendey machines. The shaper equipment consists of two R. A. Kelly, one Gould & Eberhardt, and one McDougall. A variable speed reversible motor-driven Bertram planer is also installed, and grinding machines of Landis and modern make, and one universal and one cutter grinder of the Cincinnati Milling Machine Co. Other tools include a 12 in. heavy duty motor-driven Colburn drill, a Garvin die slotter, C. M. C. power press and many other smaller tools and equipment. Bench room is provided for twenty students and individual tool racks are furnished with each vise.

Owing to the heavy demands being made on this branch of the work, the Board are equipping another room for additional first and second year students. A recent battery of about twenty small Preston engine lathes has been installed to relieve this period of instruction. It might be stated that the work performed by the boys on the machines is done from sketches or blueprints developed by themselves while in the drawing classes. It has been the aim of the instructors to so correlate the work that the interest of the boys will increase instead of diminish, each scholar continually looking forward to the completion of something he himself has started.

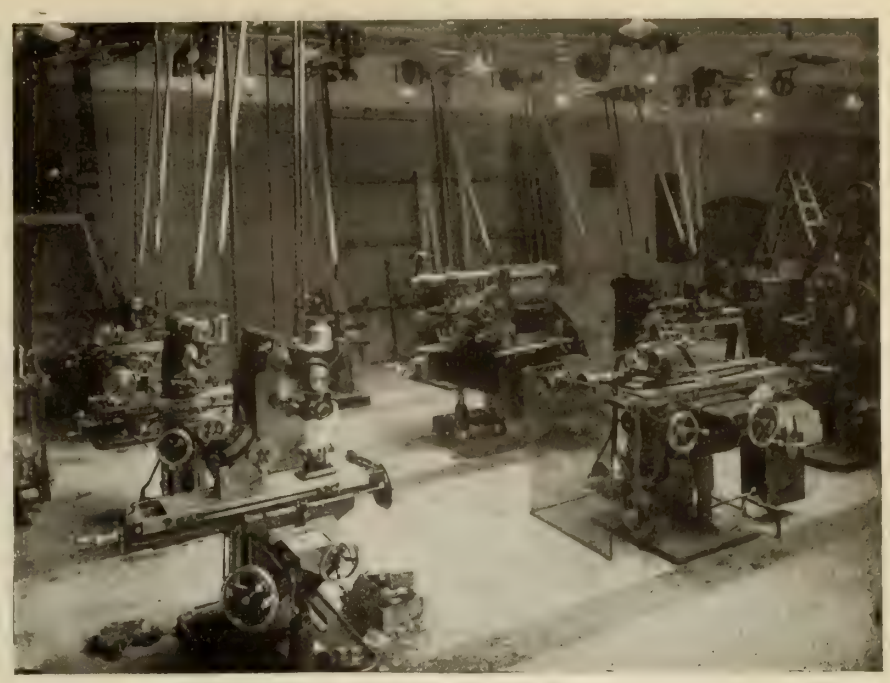
Architecture and Design

Eight class rooms are devoted to the study of drawing and designing, four for architectural and four for mechanical. From thirty-six to forty-five individual drawing tables are provided for each room. Beginners are generally given class work but more advanced students are graded and allowed to prepare drawings in keeping with their individual progress. Third and fourth year pupils in architecture, invariably work in different designs of buildings, working down from the perspective drawing, elevations, floor plans, plumbing and lighting diagrams, sectional views and constructional details. In this way the dif-

Showing top of construction room

ferent boys in the class have the opportunity of studying the various other designs while confining their actual work to the development of their own plans.

The fourth year work of machine drawing comprises separate problems in machine, electrical or structural engineering, for small groups of students, executed as far as possible under commercial conditions, lectures on the various difficulties encountered; gear designs and strength of gear teeth; cams, drafting office systems; relation of the office to the workshop production, inspection, testing, and shipping. The blackboards in all class rooms are equipped with universal drafting machines. The blue printing department is located at the top of the building and is equipped with continuous printing machine, washing and drying machines, while sun printing frames are also supplied. Parts of machine equipment have been donated by various firms to assist students in machine design.



Safeguarding Tools

A noteworthy feature of the drafting class rooms is the system adopted for safeguarding the tools and instruments of the different students. Six different sets of boys are taught in the same class room and special desks have been constructed, each having six drawers, lettered from A to F. Before the present system was developed each boy was given a key for his own particular drawer, but owing to loss of keys, or leaving them at home, with the necessity of requiring an initial deposit, caused so much inconvenience that the old method was abandoned for the one now used. A cabinet is provided with six vertical sliding boards on which hang the keys for each respective tier of desk drawers. When the class gathers the instructor pulls out the board of that particular group and stands there, while each boy removes his key and unlocks his drawer. The key is at once replaced so that a glance at the board shows the teacher that all keys are in place; the board is slid back and the cabinet locked. The boy has no further worries of the key but must take care to snap the lock when class is over.

Instruction Aids

An interesting and highly instructive method of teaching the students the problems of solid geometry is provided by means of wire models, as shown in the line drawing herewith. These forms are made in a number of shapes, such as cubes, cones, cylinders, prisms, etc., and different cross-sections are represented by plain pieces of sheet metal fixed to the wire frame, thus giving the student a clear understanding of the shape of the surface that would be exposed if the object was cut in the plane.

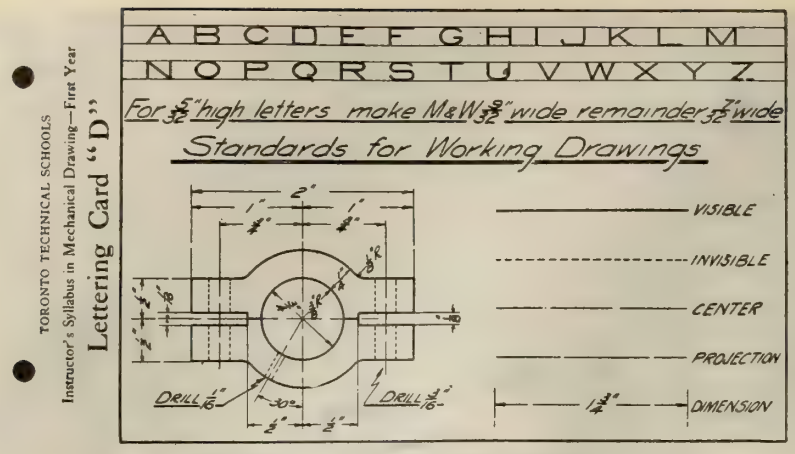
The principle of projection of views is exemplified by means of a glass case in which a model is placed and the outline traced on the glass from the various directions. When this is performed the top and ends are swung out to coincide with the same vertical plane as the front elevation. This brings the plan immediately above the front elevation and the end views to the right and left respectively, making what is known as the third angle of orthographic projection.

A small corner in the machine shop

Many other facilities are provided to make instruction as simple yet thorough as possible. Stands, which can be adjusted to any desired height, are supplied for placing objects on when the class is working on free-hand sketching. In some of the elementary classes these stands are located in the centre of a square of desks arranged about the four sides of the room, so that the representation of the object made by each pupil varies slightly from the others. This method is also followed in all the art and sketching classes.

The instruction sheets, used in connection with the drafting course, and which are printed on the school presses, are made of a convenient pocket-book size, 7 in. by 5 in., and in loose leaf style. These leaflets are handed out to the student for each lesson and kept by him in a suitable holder so that he has a complete set at the termination of the course. A reproduction of one of these sheets is shown in the accompanying sketch. Larger sheets are perforated and arranged so that they will fold within the bounds of the holder.

Chemistry Work



Seven distinct chemical laboratories are provided for elementary and industrial studies. The former has working accommodation for sixty students and lockers for five hundred. The industrial laboratories are specially equipped with apparatus for the various trades. A large fume closet is installed for the hydrogen sulphide generator used in conjunction with qualitative chemistry. The electro-plating room is provided with motor-generator to produce low voltage current suitable for electroplating, ammeters, voltmeters, tanks, etc. The laboratory for metallurgy is furnished with various types of furnaces for use in assaying and the study of metallurgical operations.

It might be mentioned that a separate room is set apart for the housing of the fine precision instruments required by the analyist. The partition between this room and the adjoining laboratories is of glass, so that a clear view of the operations can be seen by the students as the analysis is being carried on. The work benches, in this room, that support the delicate weighing instruments are attached to the main walls of the building and not to floors or partitions, so as to minimize the possibility of vibration and consequent error in the calculations.

The head chemist has made a special study of chemistry in relation to foodstuffs and the important of this science in household work is not overlooked, and it occupies a suitable place in the course of domestic science for young women.

Printing Department

One of the outstanding features of the institution is that branch of the work devoted to the study of the printing trade. The art of printing to-day contributes very largely to the general enjoyment of modern life, and facilitates the advancement of civilization in all parts of the world. The "familiarity" of the public in these days with news in print might easily "breed a spirit of indifference" to the importance that should be associated with this particular phase of industry. The printing trade, like many other activities, has had to fall in line with the universal demand for specialization, so that the apprentice or even the more advanced workman in the commercial workshop of to-day is not afforded the same opportunity to acquire

Instruction sheets issued in loose leaf form

the general allround knowledge that those boys of former days enjoyed.

In organizing the Apprentices' School of Printing as a department of the school work, it was done so not so much to relieve the printing offices of the responsibilities of teaching apprentices in their own plants, but rather to co-operate with these executives in developing the necessary craftsmanship in those striving to increase their knowledge of the art in its many branches. Printing is included in the general industrial course and a brief summary of the lessons are as follows:—practical work of learning the case, setting up straight matter, tabular matter, letterheads, billheads, menus, programmes, advertisements, etc. Impositions of four to thirty-two page forms, folding machine work, platen and cylinder press work, and make ready are also included in this course. The machine work is usually confined to advanced pupils. Many of the newspaper offices of the city have arrangements with the school officials for the younger apprentices to attend one-half day a week, the period suited to the needs of the boy's employer.

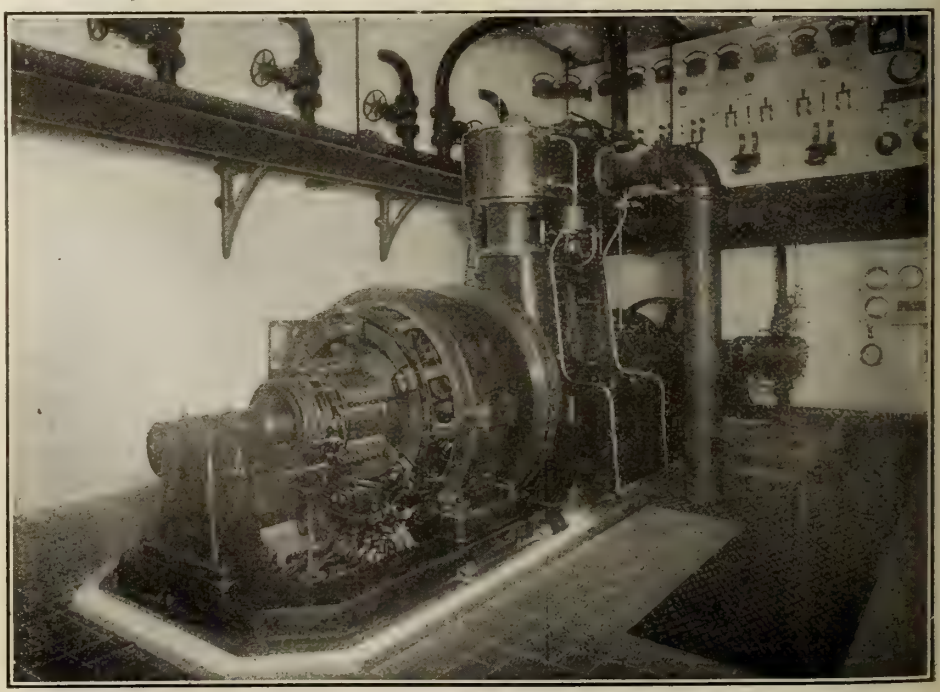
Every facility is given for the students to study the process of color work, the necessary plates being often donated by firms who have no further use for them in their catalogue work.

A point of special interest is the fact that all the printed matter used for the school work, such as record cards, instruction sheets, programmes, menus, etc., are produced in the school printing department.

The composing room is well lighted from the north and west, 48 ft. by 33 ft., and equipped with thirteen Tracey cabinets, eighteen type racks, and a large steel imposing stone. This press room, 56 ft. by 28 ft., contains a No. 3 Miehle press, a Colts Armory press, a Phoenix press, a Gordon press, a 38 in. automatic power paper cutter, hand paper cutter, a folding machine and two wire stitchers.

Model Apartment

A unique departure in the way of construction is provided in the arrangement of a suite of rooms as a model living room, dining room, bed room, bath and kitchen. The linen closet in this section, which was designed by one of the principals, has met with such universal approval that it has been copied by many other institutions and private individuals. Advanced students in art decoration and household science are granted an opportunity to demonstrate their skill and training in this suite of rooms. The writer was privileged to see a room that had just been completely decorated by three young girls, and the design and color scheme on the walls and ceiling would compare very favorably with the finished work of many an experienced artisan. Advanced pupils in domestic science are permitted to try their hand at providing a luncheon at stated figures.



Light, Heat and Power

To render the building independent of outside sources of light and power, and at the same time provide the means of adequate instruction facilities in this essential phase of industrial life, the school has been equipped with its own light, heat and power plant. The system also includes complete ventilating system of washed and heated air, compressor plant, refrigeration plant, hot water system throughout, and other accessories.

The various requirements that had to be considered in the layout of the plant, in addition to providing light, heat and power, were the securing of equipment and apparatus that would give the student an opportunity of acquiring knowledge of the various designs of power appliances which he might encounter in his future career, the distribution of air and hot and cold water to the various class rooms throughout the building, to provide a plant that could be used jointly for practical and demonstrative purposes without any loss of efficiency.

The power plant is situated 25 ft. below the basement level, and is divided into three sections, boiler room, engine room and fan room. Four 180 h.p. Babcock and Wilcox boilers are installed, these are fitted with chain-grate stokers. The coal is stored in bunkers alongside the boiler house and before being delivered to the hoppers is weighed in "Dormant" warehouse scales.

The engine room has an area of 43 by 40 ft. The principle units consist of a high-speed compound vertical Goldie & McCulloch engine fitted with forced lubrication, and rated at 365 h.p.; one 150 h.p. Corliss engine built by John Inglis Co., Toronto, this unit is direct connected to a Canadian Westinghouse generator; a Canadian Westinghouse Motor-generator set; a Canadian Ingersoll-Rand air compressor, with a capacity of 230 cu. ft. of free air per min. at 100 lbs. per sq. in.; an ammonia refrigerating machine built by the Frick Co. of Waynesboro, Pa., circulation being obtained by means of a Smart-Turner centrifugal pump. Other equipment in the engine room is of the most modern

A Goldie & McCulloch vertical engine, installed in power department

type and suitable in every way for practical use and demonstration for the students. The main switch board is located in a gallery along one side of the engine room.

Two large "Keith" fans, supplied by Sheldons of Ga t, are installed for ventilation purposes. The air washer and humidifying apparatus was supplied by the Carrier Air Distributing Co. of America. The air is drawn from the outside through long ducts and forced through a sheet of water and against heated steam pipes, so that when the air is delivered to the various rooms it is pure and of the proper temperature. This system is also used in a general way in instructing the pupils.

Evening Classes

Instruction provided for the evening classes is much the same as that for day pupils, only greater attention is required along the lines of individual supervision. This is necessary owing to the varying degrees of advancement made by the different students. These classes are primarily intended for apprentices, journeymen, salesmen, foremen, and others, who are engaged in industrial or commercial pursuits during the daytime, and who desire supplementary instruction a ong specific lines. While regular courses are scheduled for evening students no restrictions are enforced. The student is permitted to select those subjects he thinks will best aid him in his daily work.

For the convenience of those evening students who live a long distance from the school and take their lunch away from home, the school has provided two large assembly rooms where they may gather and wait until the school session commences. Metal doors are provided so that evening students may be isolated from the main corridors until the arrival of the school officials.

One of the chemical laboratories

A school store has been established within the building and all supplies in connection with the drafting course can be secured here by the students.

Every opportunity is afforded to motor students to acquire a thorough training in the mechanism and operation of different types of motor cars and engines. Cars are obtained from many sources and practical instructors dismantle and rebuild these cars with the assistance of the students.

Instruction in oxy-acetylene and electric welding are carried on when sufficient students are interested to form a class.

The plumbing and heating classes work under direct supervision of practical sanitary and heating engineers and ample opportunity is given for practical application of this teaching in making repairs and installation of equipment about the school.

School is Run On Modern Business Lines

Accurate Costs Kept in Each Department—School is Really an Education Shop in Which Is Taught Practical Work of Extreme Value—Productive Work Carries Cost of Supplies

By G. L. SPRAGUE, B.A.
Principal Hamilton Technical and Art School

THE Hamilton Technical and Art School is constructed on the unit plan. The present unit was built and occupied for school work in September, 1919. All departments of school activity were fitted into this unit with the exception of the art department. Under these conditions, temporary allotments of space were made for shop and academic work and temporary partitions were built to serve this purpose.

The new addition under construction which will be ready for occupancy in September, 1922, is a continuation of the original plan. The present factory unit is extended on Wentworth Street, connecting with the administration building which faces the corner. On Huron street, connected with the administration building, is the Girls' building, and the location of the various buildings is such as to conserve the greatest amount of land for an athletic field.

Division and Equipment

The division of space in the different units will be made along the following lines: The present unit and its extensions will be occupied by classrooms, laboratories and shops. On the first floor, will be an engineering laboratory and transformer room in which will be installed all power and lighting control for the entire plant. In addition, there will be a 40 h. p. gas engine, 25 k. w. generator set and smaller generator sets, motors and transformers for experimental purposes. This laboratory is large enough, and is laid out so that as the growth of the work justifies it, additional equipment may be installed.

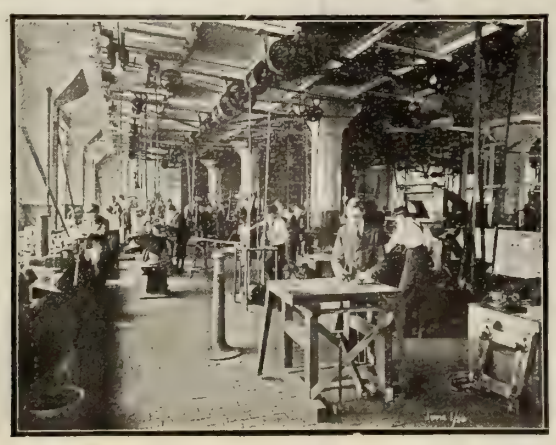
Adjoining the engineering laboratory on this floor will be a modern tool room for advanced work. During the last three years in evening class work, many machinists have become interested in tool and die making to such an extent as to warrant the installation of this advanced department. During the last three years that this advanced department has been in operation, a large number of machine tools and complicated dies have been made by pupils. This room will be equipped with electric heat treating furnace, universal milling machines, modern toolroom lathes, tool grinders, shapers and all necessary precision instruments.

Across the hall from the tool room will be a motor mechanics laboratory equipped with various types of motors, mechanical parts, carburetors and ignition systems. The present partitions will be removed on this floor and the machine shop and oxywelding departments will occupy the last two bays of the machine shop floor and the present classroom in the corner will be divided into two smaller classrooms for shop instruction.

On the second floor will be a painting and decorating shop, three classrooms, office for woodworking department, woodworking finishing room, two shop classrooms, general woodworking, carpentry, cabinet making and patternmaking shops and power machinery.

The third floor will contain two classrooms, two physics laboratories with apparatus room between sheet metal work, electrical work shop and classroom, and print shop.

The fourth floor will contain a science lecture room, a practical chemical laboratory, high school chemical laboratory, advanced chemical laboratory and drafting departments.



Co-operating With Industry

The practical chemical laboratory will be used for correlating chemistry with the industries of Hamilton by training young men for their laboratories. In this laboratory, tests will be made on steel, varnishes, oils, paints, dyes and materials connected with textile industries. The Technical high school laboratory will be used for the regular department of education courses in chemistry, junior and honor matriculation. The advanced chemical laboratory will be used for practice and theory in quantitive and qualitive analysis.

Re-distribution of space in the present unit and its extension is made on the showing the different shops have made during the last two years. The allotment of space is according to the demonstrated needs. The temporary partitions were constructed in such a manner that enlargement of shops can be made at a minimum cost.

The main or administration building will contain, on the basement level, a gymnasium, one of the largest in the province, and a modern heating plant. On the first floor will be a lunch room for boys and girls, and boys' and girls' waiting room with cafeteria service providing lunch at cost. On the second or main entrance floor will be an auditorium seating 1200, an exhibition and committee room, administration offices, class room and reading room. On the third floor will be seven classrooms. The fourth floor will be occupied by the art department containing two classrooms, freehand, clay modelling, commercial design, elementary antique, advanced antique, life, portrait, oil and water painting, china painting, kiln room and director's office. This floor will have special sky lights in the roof to provide the finest kind of lighting for art work.

On the first floor of the girls' building will be three classrooms and a commercial department; on the second,

Left hand view shows part of machine shop while other illustration shows the automobile section busy at work

three classrooms and millinery rooms; on the third three classrooms and sewing rooms; on the fourth, two cooking laboratories, a classroom, a laundry, kitchen and dining room and bedroom for home nursing.

The complete plant will contain 36 classrooms, 11 laboratories, 23 vocational or trade shops, gymnasium, heating plant, auditorium, library and reading room, lunch rooms, locked rooms, administration offices, and a fine athletic field.

Day Courses

Day courses at present comprise general industrial, special industrial and technical high school work. A boy or girl may enter the technical and art school upon reaching the fourth book. In the first two years of the general industrial course, they would cover the regular academic work of the junior and senior fourth book and qualify to enter the high school course. In addition to the academic training, pupils receive instruction half time in vocational shops. The school day is six hours long, three hours of which is spent in classroom work and three in shops. By the time a boy completes the second year he has a fair idea of the operations and theory underlying various trades and is in a position to choose, either to follow the technical high school course leading to the university or to specialize in some trade.

The special industrial course consists of instruction in mathematics, English, literature, history, and civics, and related drawing and science. In this course, pupils are given a considerable amount of time in the shops where they are trained on productive work. For example, special trade pupils are engaged in the machine shop on commercial trade orders, production orders consisting of machine tool parts and machinery; in the motor mechanics, in the actual overhauling of automobiles, five or six of which are in this shop continually. These automobiles are placed in there by outside owners for the very complete overhaul which is made in this shop, and they pay sufficient for the work to cover all costs and give a profit to the school. In the carpentry, cabinet making and pattern-making shop, productive work is the rule. Teachers' classroom desks, bookcases and other school furniture, as well as outside orders, are handled by special trade pupils. In the practical electrical work shop, pupils construct special transformers for the trade, house transformers and toy transformers, electric motors, electric irons and other special electrical work which cannot be obtained anywhere else in the city.

The print shop pupils do all the board of education printing except the minutes. All technical and art school day and evening calendars and other publicity material is set up by these pupils. The drafting department designs all wood, machine and electrical work required. At present, special trade pupils in this department are turning out floor plans showing the layout of equipment in different departments, detail drawings of desks, and laboratory tables. The result of this productive work training for special trade pupils is that they have a grasp of actual trade conditions, so that when they find employment in their trade, either as apprentices or improvers, they advance more rapidly and are of more service to their employers. Actual shop conditions are approximated in this work all along the line.

The technical high school course is for pupils who look forward to taking an engineering course in the university. In addition to the regular academic work, required by the department of education, these pupils study pattern-making, machine shop practice, electrical work, drafting and machine design, all of which is a material help to them when they enter the faculty of applied science.

With the addition of a Girls' building, the courses in sewing, millinery, commercial work, domestic science and dietetics, will be further developed. Courses will be organized to qualify pupils to enter Lillian Massey Hall, Toronto University, and Macdonald College, to train for teachers of domestic science.

An Education Shop

Six years ago, the present management undertook to develop the technical school into an education shop, in which educational values should not be sacrificed, but rather increased as far as related to special trade pupils. This effort has been attended by a considerable measure of success. Junior trade pupils work on exercises until the instructors are satisfied that they are ready to proceed with productive work. The reason is obvious. They must learn how to handle tools before they can be trusted with valuable material. The amount and character of productive work, both for the school and commercial orders turned out each year, is surprising.

For example, the practical electrical trade pupils installed the electrical wiring in the chemical laboratories, the domestic science laboratory, the electrical engineering laboratory, the practical electrical shop and the print shop. In addition, they have manufactured transformers, electric irons, washing machine motors and performed other special electrical work on commercial orders. The woodworking special trade pupils constructed, during the last two years, over sixty teachers' classroom desks for the board of education, and a large amount of special school furniture for the school. The machine shop trade pupils have made seventy-five per cent. of the special machine tools required, such as reamers, drills, milling cutters, arbors, lathe face plates, lathe chucks and special dies. The motor merchanics pupils have overhauled and rebuilt practically over a hundred automobiles during that time.

Earns Operating Supply Costs

During the last year, the productive work of special trade pupils has carried the cost of all supplies required for the operation of the entire school. The average public school manual training shop is a clear outgo as far as expenditure is concerned. If the technical school were operated along the same lines, it would cost the taxpayers about ten thousand dollars a year for the supplies. Under the present management, it does not cost taxpayers a dollar. During the last year, the productive work has brought in enough to purchase all office, classroom, drafting, cooking, sewing, millinery, print shop, electrical shop, woodworking shop, machine shop, and motor mechanics shop supplies, also to cover the cost of publicity and chemical

View to left shows woodworking department. Right hand illustration shows physics laboratory

laboratory supplies, leaving a small margin of profit.

Business Organization

To accomplish this, the school is organized along business lines. There is a production system. Shop orders cover every class of work undertaken in the shops. Material and stores records are kept and each shop is debited with supplies and credited according to receipts obtained from work done, or material sold. There is a regular purchasing system with card price record, keeping the management acquainted with the varying cost of materials and supplies, A cost accounting system keeps record of detailed costs in every department of the school, so that it is possible for the vocational committee to know just how much the operation of the school costs. By this means, the cost of technical education to the taxpayers is confined to fifty per cent. of the cost of buildings and equipment and two-thirds the cost of instructors' salaries, and, in addition, caretakers' salaries and coal, power and light.

Instruction of Apprentices

In addition to regular all-day courses, special instruction is given to apprentices from over twenty firms one-half day per week. These apprentices come from the following trades:—patternmaking, machine and tool making, electrical work, drafting and printing. Related mathematics, drawing and underlying sciences of the trade comprise the course of instruction given. Printing apprentices from all news and job print offices study composition, advertising design and linotype operation. The progress made by apprentices in this shop and in other branches of apprenticeship has proved very satisfactory to employers for the last six years. Employers in Hamilton have continued this plan of part time instruction of apprentices voluntarily because the apprentices who have been permitted to avail themselves of this opportunity, have shown improvement in their several trades.

The enrollment during the year 1921-22 in day classes has averaged more than 700, over 600 of whom are boys. The girls' department is limited to 100 because of lack of space in the present unit. The new addition, together with the present unit, will provide room for 1200 all day pupils and over 1000 part time pupils.

Provision for Instruction of Permit Workers

When the provisions of the Adolescent Act requiring the attendance 400 hours each year of all minors between 14 and 16 years of age who are at work, goes into effect in September, at least 1000 will have to be taken care of in the technical school. In order to provide instruction, for number of hours specified in the Act it will be necessary to have an organization of courses and staff on lines differing from the all day courses. It is planned to operate these classes from 8.30 a.m. to 12.30 a.m., and from 1.00 to 5.00 p.m., five days a week and fifty weeks in the year.

By this plan, permit workers could be allowed to attend two different days each week. The four-hour period of instruction could be divided equally between classroom and vocational instruction. This method would simplify the problem from the employer's standpoint and at the same time meet the provisions of the Adolescent Act. This plan is proposed because there will always be a considerable number of boys between 14 and 16 years of age compelled to go to work for economic reasons and another class of boys of the same age who would be far better for the discipline of regular employment. The provisions of the act are wise in providing for the part time instruction of permit workers of this age. Statistics show that the majority do not possess a good elementary education before leaving school and the requirements of good citizenship make it incumbent upon the government to continue their education on a part time basis. When this forward step in education has been given a fair trial in a reasonable period of time, employers will approve of it. Several States to the South have carried on similar plans for part time instruction of permit workers of this age and after a decade of experiment found it perfectly satisfactory both from the standpoint of the employer and the citizenship.

During the year 1921-22, over 3700 pupils have attended the evening classes in 50 different courses. The range of subjects is indicated by the following list:

Arch. drwg., 1st year, arch. drwg., 2nd year, carpentry, 1st year; carpentry 2nd year, care and oper. autos, (men), care and oper. autos, (women), chemistry, analytical, chemistry, fundamental, cooking 1st year, cooking 2nd yr., dressmaking, electricity, 1st year, electricity 2nd year, electricity, 3rd year, electrical workers, elementary boys, (Sr. 3) No. 1, elementary boys (Sr. 3) No. 2 elementary boys (Jr. 4) No. 1, elementary boys (Jr. 4), No. 2, elementary boys, (Sr. 4), No. 1, elementary boys, (Sr. 4) No. 2, elementary girls, (Sr. 3), elementary girls, (Sr. 4), French, commercial, and linotype operation.

Then we have machine drawing, 1st year, machine drawing advanced, machine operation, millinery, motor mechanics, oxy welding, patternmaking printing, sewing, plain, sheet metal drafting, Spanish commercial, shop math., 1st year, shop math., 2nd year, shop math. 3rd year, stationary engineering, structural steel design, telegraphy, toolmaking, woodworking, 1st year, woodworking 2nd year, showcard writing and sign painting, commercial designing and china painting, clay modelling drawing from caste, still life painting and freehand drawing.

In motor mechanics and care and operation of automobiles, pupils were mostly garage workers, chauffeurs, truck drivers and car owners. One class of 12 pupils in one motor mechanic class operate on their own responsibility, a night service garage up town three evenings a week, where they are applying the instruction obtained at the technical school and at the same time making a profit. The instructor visits them each evening and when they get stuck on any class of work, explains it to them and they go ahead with the work. In patternmaking, pupils were mostly apprentices who were given the opportunity to do a class of work they have never been trusted with in the place where they are employed. The class in stationary engineering is composed of engineers studying for their certificates. They have followed the course laid down by the department and

Pattern-making department to left. Other view shows electrical department.

How to Place Equipment In Technical Schools

Manufacturers and Dealers Should Get In Touch With Secretary of Advisory Committee Mentioning Type of Machines They Have to Offer—Give Fullest Particulars in Order to Avoid Delay

HOW ARE purchases of equipment made for the various technical schools throughout the country? How can I sell the machines I manufacture, or handle to such schools? Manufacturers and dealers are vitally interested in both these questions, so Canadian Machinery, went to those in charge, asked for the official procedure and following is the information we received:—

First of all each technical school is under the management and control of an advisory committee. This committee is appointed by the board of education, and is composed of an equal number of persons belonging to the board. The gentlemen not belonging to the board, half of whom are employers, and half of employees, are chosen from the representative industries of the community. Such an advisory committee is intended to ensure a close relation between the work of the school and the needs of the local industries.

This committee has full charge of the establishment and management of the technical school, including the erection of buildings, the installation of equipment, the appointment of teachers, and the courses of study, subject to the regulations of the government and the approval of the school board.

The advisory committee may appoint a special committee for the purpose of determining the type and amount of equipment to be installed, and the secretary of the board is also secretary of the advisory committee. Manufacturers and dealers should communicate with the secretary of the board in making proposals for the sale of equipment.

Provincial grants are paid to local school authorities in support of the technical classes. These grants are paid on maintenance charges and on capital account for the purchase of equipment, or the erection of buildings.

When a local advisory committee has decided to purchase a machine or piece of equipment, they recommend to the board the desired purchase, then if the recommendation is accepted by the board, it is submitted to the department of education to see whether the government will pay a grant on the cost of the machine or equipment. The committee may make the purchase without the approval of the department, but in that case they will receive no grant on the expenditure.

As a general rule the type of machine needed in a technical school is the ordinary, commercial, up-to-date article of good quality, such as is used in the common machine shop. Special duty or one operation machines, or heavy duty machines as a general rule find no place in a technical school. On the other hand the machines must be heavy enough to turn out a good job of moderate dimensions. Combination machines designed to perform the duties of a number of machines are not satisfactory in a technical school shop.

Examples of the type of equipment usually found in a technical school are as follows:—

The woodworking mill room should contain a surfacer, a variety saw, a jointer, a band saw, four to six speed lathes, and a boring machine or hollow-chisel mortiser. Other machines will be found only in the larger schools.

The machine shop should contain from three to ten engine lathes, a shaper, a milling machine, a back-geared drill press, a sensitive drill, a hack-saw, a forge and anvil, and a tool grinder. In the larger schools the number of these machines may be greater, and other machines such as a planer may be added. All of these machine tools should be ordinary, standard, good quality articles, not heavy duty weight, or not too light in weight.

The lathes should be about 14 inch by 6 feet capacity. Lathes with a wide gap or a long bed are not ordinarily needed in a school. At least one of the lathes should be of the open train gear type, while the others may be quick change. At least one lathe should be fitted with a taper attachment. The question of whether the lathes should be all of one make or should be of different makes and types is an open one, with much difference of opinion about the matter. The weight of opinion seems, however, to favor the installation of a variety of makes. At least one lathe should be of what is called tool-maker's quality and design.

The method of drive varies greatly with local conditions, but generally the wood working machines have individual motor drive, while the iron-working machines are group driven from shafts.

Good Results From Individual Instruction

By GEO. W. ROBB
Principal Industrial Classes, Orillia, Ont.

THE ORILLIA evening industrial classes were organized in January 1920, and this is the third year of their existence. This year on account of the business depression and consequent reduced factory staffs, the initial enrollment for these classes, in Orillia, as in most other towns, was smaller than in previous years. In spite of this the board of education decided to carry on and classes were formed in millinery, dressmaking, arithmetic, English, mechanical drawing and shop mathematics. The classes opened on Nov. 22, and have been held on Tuesday and Thursday evenings from 7.30 to 9.30 and will continue until the end of March.

During the first year temporary rooms were used. Last year permanent quarters were secured, and several rooms in the central public school were fitted up.

The arithmetic and English class was organized to meet the needs of those who had not completed their public school education and also for those preparing for more advanced work. The work is largely individual and the subjects are taken up on alternate nights under Miss G. Watterworth, and Mr. J. C. Smith of the Collegiate staff.

Personally I have been in charge of the class in shop mathematics, and the text book used has been Warren and Rutherfords "Mathematics for Technical Schools." The course has however been modified to meet the needs of the class nearly all of whom are machinists.

Mr. E. G. Arens head draughtsman of the E. A. Long Co., has been in charge of the class in mechanical drawing. This has been a beginners' class this year, and the class started with the plain drawing objects, followed by freehand drawings of actual objects and complete detailed drawings from these sketches. At present the class are inking in the development of plane and curved surface and to complete the work for the year will make a detailed assembly drawing of some part of a machine, making a tracing of it.

Excellent work has been done in all the classes and the majority of students have shown their interest and appreciation by their regularity in attendance.

It is a matter of regret however that more have not taken advantage of these classes.

EFFICIENCY AND COMPRESSED AIR

Air when compressed and converted into a form of energy and power ceases to be "free;" fuel, machinery, equipment, and labor enter into making it an item of cost. And the cost of compressed air greatly rises, through any waste by leakage before final distribution to the tool which it operates, or to the points of its ultimate use. Due to leaks through joints in piping, valves, split pipe, defective castings, and wastage at a tool or machine, the over-all efficiency of compressed air is very often reduced 40 to 60 per cent. throughout the system.

Cutting Production Time in Four

Grinding Method Which Reduced Operation Time Seventy-Five Per Cent. and Increased Accuracy—Rounding Gear Teeth on Milling Machine—Producing Long Shaft on Automatics

By J. H. MOORE

TO IMPROVE production methods is the aim of every ambitious and successful executive. He is never content to lay back on his oars and say "Well we are turning out piece E.G.6 at 40 per cent. what it cost us three months ago." Instead of this self satisfied attitude, he is encouraged by his former successes, and is determined to go them one better in the next attempt. He is continually on the lookout for new methods of machining, and it is this idea which prompted the present short article. It will only scratch the surface so far as varied methods of performing different work is concerned, but perhaps among the ideas shown, one or two may be applicable to other plants. No particular type of work will be considered, but rather a few scattered examples of different opperations.

Automatic Work

Quite often a piece comes up, which at first sight looks too complicated for automatic work. Before making up your mind on such an important point it is always well to study the part very carefully, and if you are anxious to make it on an automatic, and are not yet quite convinced as to its feasibility. do not hesitate to ask for the benefit of the experience of others, viz, makers of such tools. Even if you do not use one of their machines, ask them anyhow, for you will find they will be only too willing to impart information.

Take for example the piece shown at Fig. 1. This is a rather unusual part for an automatic, yet it is being successfully made on a 3-in. multiple spindle machine. Fig. 2 shows the detailed tool layout of the part being machined, and from this all information of a mechanical nature can be gleaned. Fig. 3 shows the machine in actual operation.

At Fig. 4 we see a 1¾ multiple spindle automatic screw machine specially equipped for handling long shaft work. This view is taken from the forming side, but the length of shaft is clearly shown as 11-3/13-in. under the head, emphasizing the unusual nature of this type of piece for automatic work. The average conception of work suitable for automatic machinery is something not

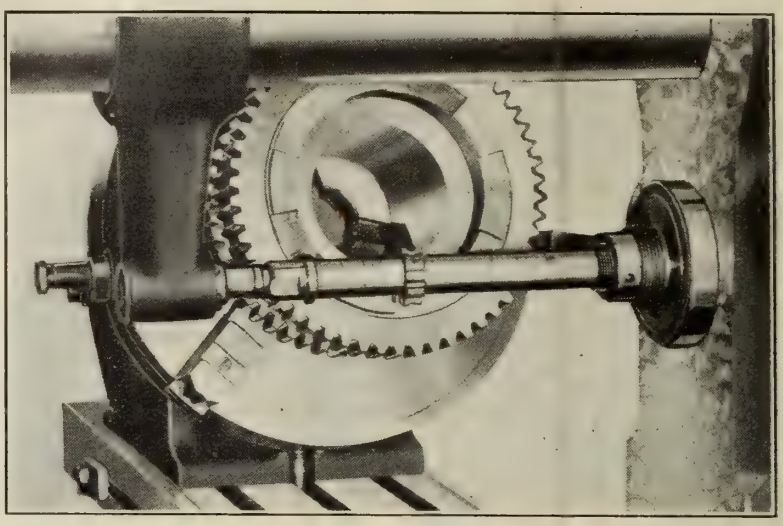

Fig. 6.—Rounding edges of gear teeth

The following firms were good enough to allow us the use of illustrations in this article: Figs. 2 to 5, National Acme Co., Cleveland, Ohio; Figs. 6 and 7, Rockford Milling Machine Co., Rockford, Ill., and Fig. 8, from Norton Co. of Canada, Hamilton, Ont.

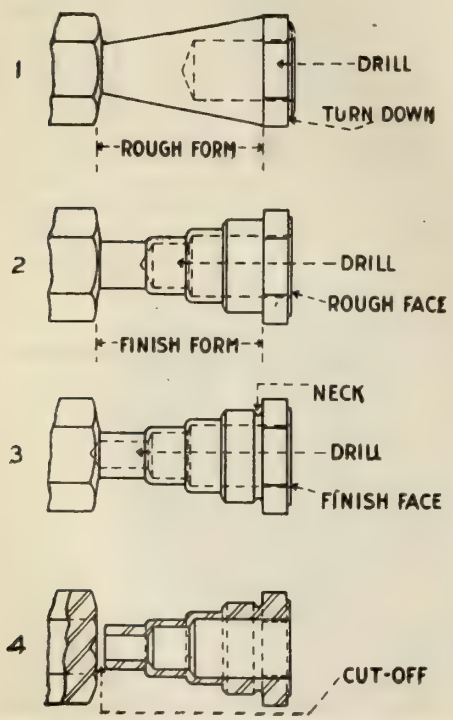

Fig. 2.—Tooling layout for piece shown in Fig. 1

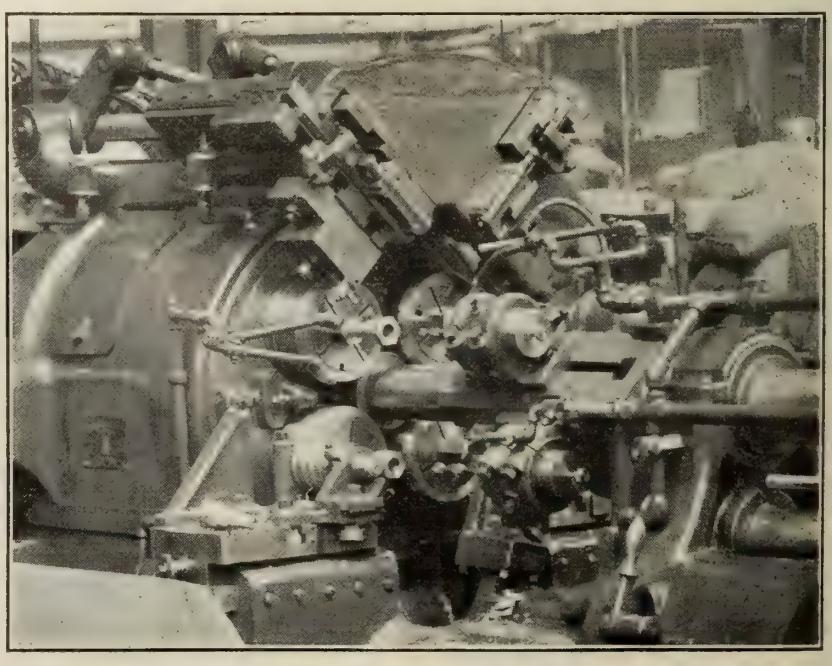

Fig. 3.—Multiple-spindle automatic producing piece shown in Fig. 1

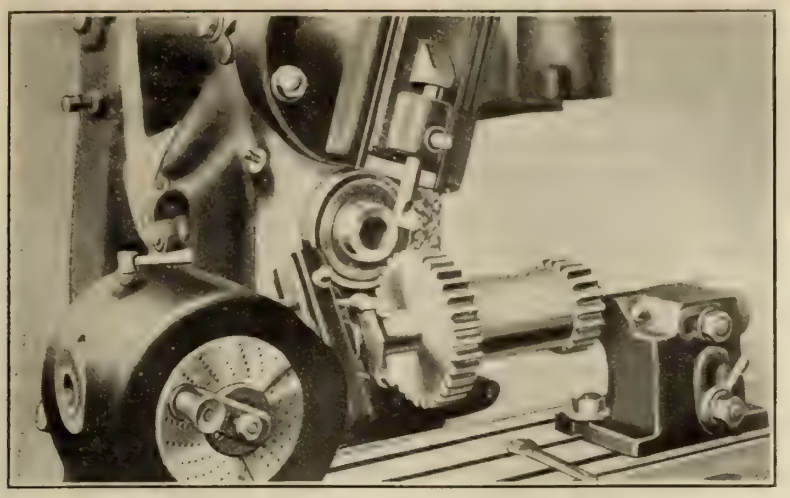

Fig. 7.—Special method of rounding gear teeth made of alloyed steel

too large or too long. Of course, this is an erroneous idea, and as mentioned previously, when in doubt ask for information.

In Fig. 5. we see the cutting off side of machine on the same shaft, and following is the list of operations. In the first position, the piece is turned for one third under head with auxiliary slide, and one third with a special turner.

In the second position one third is turned with special support and end is faced with stud turner.

At third station, the head is broken down and chamfered with a double deck cutting off tool and forming tool holder, while at the fourth position, the shaft is cut off and the stock fed out 11½-in. A special stock stop and stock feed is provided in the equipment on this machine.

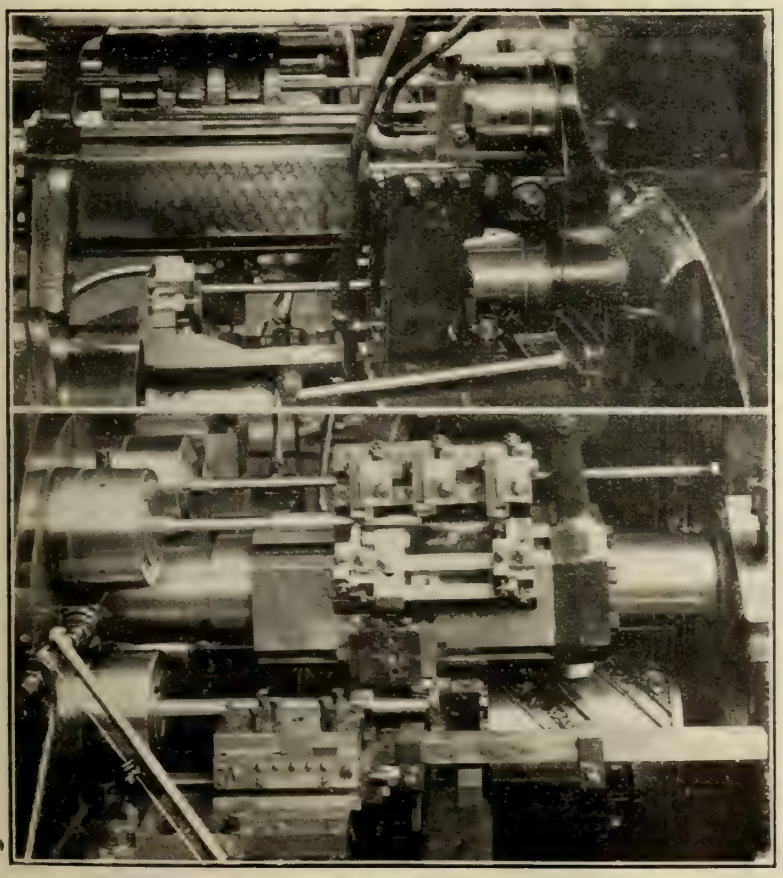

Fig. 4.—Automatic working on long shafts
Fig. 5.—Cutting-off side of machine

Milling Problems

The next two examples of parts completed are performed on the milling machine. Fig. 6 shows a steel gear held in a chuck on a dividing head, the teeth being rounded by means of the form cutter shown. This method of rounding teeth is out of the ordinary, yet it was found to save a lot of time and money for the firm using this method.

Another gear tooth rounding operation is shown in Fig. 7. In this case the gear is made of alloyed steel and it was found very inconvenient and costly to round the teeth on a regular gear tooth rounding machine. After adopting the plan shown in their own manufacturing plant, the firm allowing us the use of this photograph was able to save considerable time and money, and the time required to round each tooth is only four seconds. The gear is 8 pitch, and a regular 10½-in. dividing head was used in this case, as well as in the operation shown at Fig. 5. These two photographs prove conclusively that milling machines are exceedingly versatile, providing executives, give them a chance to show their versatibility.

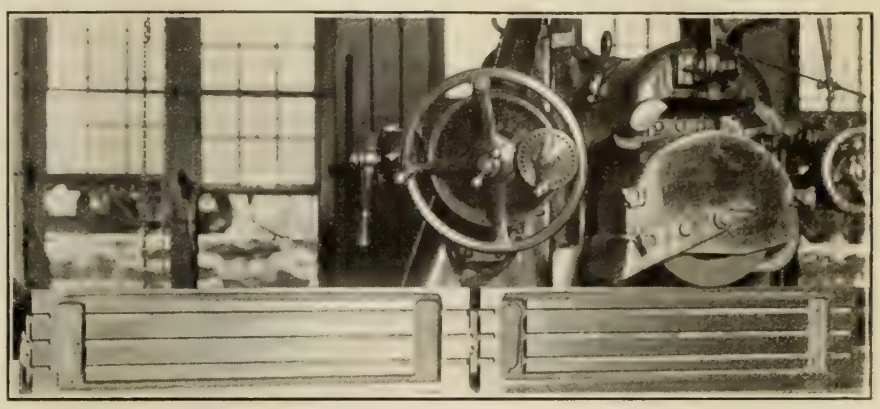

Fig. 8.—Surface grinding the sides of two milling machine tables

Grinding Tables

In going through a machine shop, there is perhaps no other work which impresses the casual visitor as more laborous or out of keeping with present day production methods than the scraping of ways of machine tools, or tables for the same. For some considerable time it was considered impossible to eliminate planing and scraping, but later, when grinding reached its present high state of perfection, this viewpoint was changed. Extremely accurate surfaces are now obtainable by means of grinding machines, and work is often completed in a fraction of the time necessary when planing and scraping is adopted. After the grinding no scraping is necessary unless the conventional frosted effect is wanted.

Fig. 8 shows a 10-ft. surface grinding machine surfacing the sides of two mil-

Students Visit Factories With Good Results

Academic and Practical Training Combined—Co-ordination and Co-operation Essential In Various Classes—Woodworking, Mechanical Drawing, Physics, Chemistry, Machine Shop Practice, and Many Other Lines Are Covered

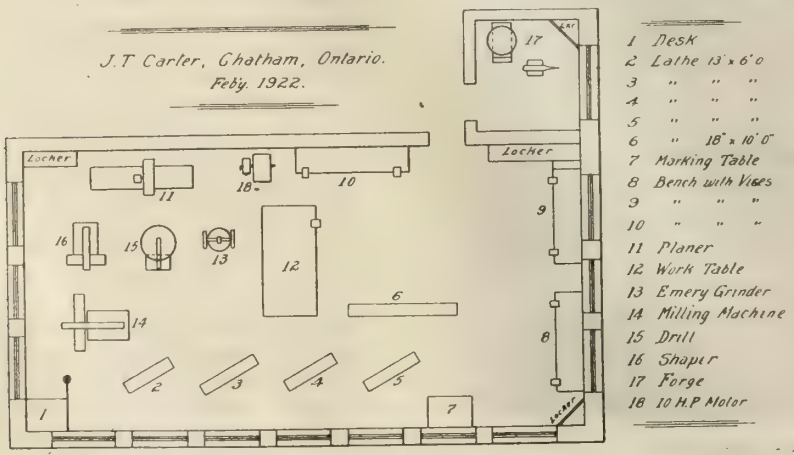
By HARRY COLLINS
Principal Chatham Industrial School

AN ACCOUNT OF technical education in the City of Chatham may be accepted as a type of what perhaps with certain modifications and variations, is being accomplished in other cities with a population of about fifteen thousand and an average number of industries.

For the past four years what may be regarded as the nucleus of a technical school has been carried on in certain rooms of the Central (public) school, a building as its name implies, occupying a central position in the city, a factor of importance especially in connection with night school classes.

Conditions, as is the case with most beginnings on a small scale have not been ideal, but they have been sufficiently favorable to test out the general idea. We have gained much valuable experience and necessary information before launching out into larger expenditures required for more pretentious quarters and more varied equipment.

In brief, our experiment here has demonstrated the real need for training along technical lines, as well as the desire on the part of employees to take advantage of even the somewhat limited facilities so far provided.



Thanks also to the splendid assistance rendered by the provincial and federal governments, both by way of substantial money grants, and by expert advice freely and cordially given by the Director of Technical Education and his able staff of assistants, the experiment in Chatham as elsewhere has not been a financial burden on the municipality, but has proceeded along safe and sane lines. In difficulties and discouragements incident to beginnings, the sympathetic and helpful attitude of the Deparment has been most timely.

Academic training goes hand in hand with the practical work of the shop. For example, when the student is using the micrometer and the vernier in the machine shop, the opportunity is seized to stress that department of the work in arithmetic, with a number of examples to be worked out by the pupil. Vice-versa, when the relation of temperature and pressure to the volume of a gas is being taught in physics, or the curve of solubility in chemistry, the good services of our mechanical drawing master are secured and accuratetly drawn graphs are made. Co-ordination and co-operation are essential in the various classes of a technical school, and they can be worked to advantage nowhere better than in the small school.

This account of technical education is necessarily limited to what is being done for the boy. The work for the girls proceeds along similar general lines based on the same general principles of co-operation.

The course at present is a three-years one, the first being of a preliminary nature, and omitted in the case of the more advanced student. The special subjects of the first year are woodworking and mechanical drawing. From the simple drawings made in class, the boys make models to scale in the woodworking shop, so that the drawing is a practical proposition from the beginning. These models are varnished and kept on exhibition, so that there is every incentive given to the boy to good workmanship right from the start. These models are also of assistance in our night drawing classes, where co-ordination of work is not so easy of attainment.

The advanced classes in drawing take up all branches of machine drawing, lettering, etc., and also have made industrial maps of the city and blue prints which have been used by the Chatham Chamber of Commerce as covering their requirements.

Showing Mr. Carter's conception of an ideal technical machine shop layout. Mr. Carter is a student in the school at Chatham.

The boys of the school, under supervision of the master, have also undertaken the installation of all machines, including line shafting, making of guards, work benches, and other accessories. In all cases where necessary or desirable, drawings of the work to be done have first been made, and the work has been thoroughly discussed in the class room in as informal a manner as possible. The boys are encouraged to express themselves freely without that stilted and formal style peculiar to some class rooms. Debates are also held at intervals on general as well as on special problems.

In the woodworking shop we have the following equipment:—

1 band saw motor driven direct; 1 small lathe motor driven direct; 1-9 in. x 10-ft. lathe run off line shaft; 1 disc sander; 1-12 in. jointer; and 1 combination rip and cross cut circular saw.

We require, but with our present accommodation have no room for, 1 emery grinder; 1 vertical sander; 1 tenon and mortise machine, and 1 medium sized lathe.

Besides the models already referred to, our boys have made very creditably a varied collection of table lamps, piano lamps, candlesticks, indian-clubs, rolling pins, wands, chisel-handles, book-racks, medicine cabinets, tables, a particularly fine office chair, and on one occasion during the Flu epidemic, to help out a local undertaker, the boys made fifty rough boxes. In the latter case, for obvious reasons we have not repeated the experiment. This work has been done in most cases from carefully sketched designs.

Machine Shop

Our machine shop equipment is as follows:—1-10 h.p. motor running line shaft; 1 Hendy milling machine; 1 Hendy shaper; 1-13 in. x 6 ft. South Bend lathe; 1-13 in. x 6 ft. Perfect lathe; 1-18 in. x 10 ft. C. M. C. quick change lathe; 1 London drill press; 1 double emery stone on stand; 1 power hack saw; 6 vises; 1-24 in. x 30 in. marking table; 3 work benches with vises; a collection of dies, etc.

We need another lathe, a grinding machine and other sundries, but shall probably not be in a position to handle these until we secure more commodious quarters. This question of a new building is our largest problem at the present time, and a special committee has the matter under serious consideration. Towards this end the Department of Technical Education has already made an exhaustive industrial survey of the City of

Chatham, and fifty copies of the same have been circulated among prominent parties and organizations.

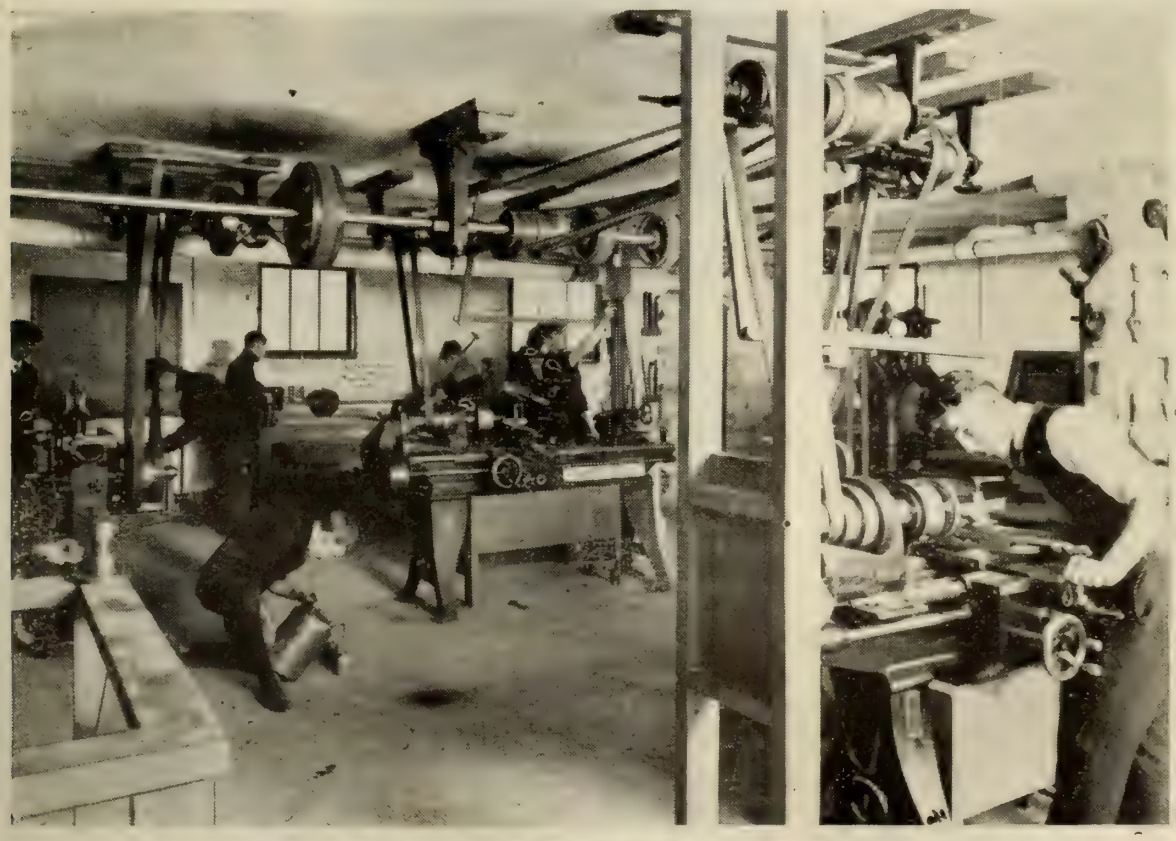
The work done by the boys in the machine shop covers all forms of elementary machining, including bolts, spur and mitre gears, studs, etc. As in the case of woodworking, the work is done from drawings made in the drafting room and care is taken to see that the boys clearly understand each step of the process. During the past term, the workers in the night classes have turned out a very creditable single-cylinder gasoline engine, which ran without any trouble on the first attempt.

Visit Factories

Another phase of the work which we find valuable for many reasons is visiting the various factories in our district. Before visiting a factory we discuss what we are looking for. For instance, we visited the Dominion Sugar Company's plant to inspect among several other things, the practical application of a law in physics that we had studied in the class room, namely that a liquid boils under a vacuum at a much lower temperature than the ordinary boiling point. We have also visited in connection with other science lessons, such plants as acetylene welding, storage battery stations, garages, and spent considerable time on the open model of the Gray-Dort automobile at their sales room.

We also visited many other plants, large and small, and at a small electroplating plant the boys had that department of electricity clearly explained, and incidentally copper plated everything in their pockets that lent itself to that purpose. They have also visited the local hydro station several times and inspected the transformers and other equipment.

Our shop master has of course used this method considerably, visiting foundries, woodshops, machine shops, etc. We take care that time is not wasted in desultory wandering about a plant, which amounts to little more than idle dissipation. After a visit the various points of interest are discussed, and tests of observation given. Sometimes essays are assigned on various topics connected with the trip.



In technical education, as in fact in all kinds of education, much depends on the teacher. I know of no position demanding more exacting qualifications for a successful teacher than that of the shop master. In our school, the one teacher takes mechanical drawing, woodworking and machine shop practice. Fortunately we have a man who combines in a marked degree, the qualities of an excellent mechanic with that great quality of sympathy which wins at once the confidence and respect of the boys.

Our boys also take physical exercise but largely in the form of games. Baseball, basketball and football are the favorites. We have a team entered for showing. The industrial world needs and they have each year made a good showing. The indusrtial world needs good clean sports as much as it needs anything else, and our technical schools can do much in that direction.

Finally we need in our Technical school work, well balanced advisory committees. In Chatham we feel we have been singularly fortunate in securing right kind of men, our committee being well balanced between employer and employee. The members of the committee visit the day and night classes from time to time, and as a slight appreciation of their good work, the domestic science class puts on occasional luncheons which are declared to be unsurpassed by even the most exclusive chef service of our best hotels. Indeed one feels in writing an account like this that it is onesided in that it leaves out perhaps in some ways the better part of much of our work namely among our girls.

One of the members of our committee is this week entertaining a party of one hundred and twenty-five to an evening affair, that judging from past experience will be one of the real social affairs of the season. To get the general public interested in this training is an important part of the work of the principal and the advisory committee. Last year we had nearly fifteen hundred people visit our annual exhibition. Nearly one thousand dollars have been donated by various industries for scholarships for our day school classes and many prizes for night classes. We feel grateful to the public for many manifestations of interest in this important work of trying to help those who help themselves.

A descriptive booklet has just come to hand from the Bausch & Tomb Optical Co., Rochester, N.Y., covering their lines of metallographic equipment, featuring those outfits in which the inverted form of microscope is employed.

Partial view of machine shop in Chatham Industrial School

Wide Range of Instruction is Being Given

Subjects Cover Machine Shop Practice—Automobile Mechanics, Welding and Cutting, Mechanical, Structural and Mechanical Drafting, and Other Important Trades—Prizes Offered

By W. W. NICHOL, B.A.
Principal Ottawa Technical School

AN attendance of 5,000 students at the Ottawa Technical School being an increase of 1,000 over the year before and nearly 4% of the total population of the city is reported. This evidences, on the one hand, the very laudable ambition of the workers of the city for self-advancement along vocational lines, on the other, the fact that the school authorities have been leaving no stone unturned to provide the means by which this ambition may be realized.

The industrial vocational committee is to be congratulated on the results which have crowned their energetic endeavors. The new shops' building, which was completed last year, has accommodation for the following departments: machine shop practice, automobile mechanics, plumbing and steamfitting, building construction, painting and decoration, oxy-acetylene welding and cutting, electricity, chemistry, printing, mechanical, structural and architectural drafting. This with the accommodations already in use will give opportunity for imparting a very wide range of instruction in the practical arts. The committee has installed the most up-to-date approved educational equipment, and has provided instructors well known in the city as high grade master mechanics and experienced draftsmen.

Machine Shop

The machine shop is considered by experts to be particularly well equipped and laid out. The equipment comprises a Browne & Sharpe universal milling machine, a Ford-Smith plain miller, a planer, shaper, several different types of drills and grinders, an arbor press, hacksaws, vises, etc. There is a regular battery of lathes of the best commercial type. All the machinery is electrically driven from overhead motors on the group system. The tool room is fitted up in standard fashion, a place for everything, and everything in its place. Tools and other material in store checked out and in as required. Tool room management is part of every student's instruction. Adjoining the shop is a class room with equipment for special instruction in machine shop mathematics, calculations of speeds, feeds, etc. and for general instruction in the use of shop hand books, etc.

Besides the regular day pupils a large number of machinist apprentices attend special classes during each day. Their number has recently been augmented by some of the older men in the trade temporarily unemployed. The smithy which serves both the machine and automobile shops contains an electric forge and all necessary tools and accessories. An oxy-acetylene welding and cutting plant is installed and a Stewart triple-purpose furnace consisting of a No. 21 barium chloride furnace, a No. 28 oven furnace and No. 3 furnace for high speed steel complete with blower. The installation of an electric welding plant which is now contemplated, will make the department complete. Mr. J. D. Young, formerly of the International Marine Signal Co., and the department of marine is in charge.

Owing to the importance of the automotive industry and the popular interest taken in the subject the committee have spared no expense in fitting up the motor mechanics rooms. All the appliances used in the most up-to-date repair shops have been purchased and the students have a regular array of cars of

Machine Shop

the best known makes to work on. The instruction is most practical and no boy who goes through the course should have any difficulty afterwards locating a good situation. In the lecture room upstairs there are many pieces of sectionalized equipment, including an Armstrong Whitworth engine, Delco ignition and Stewart vacuum systems, Stromberg and Schebler carburetors, magnetos, etc., etc. No less than twelve evening class groups are enrolled in this department. The teachers are Messrs. T. C. Row and S. Clemens. The former is head of the department and regular day instructor. The value of the equipment in this and the machine shop will run very close to $20,000.

Woodworking Dept.

The woodworking shop is a large well lighted room equipped with 24 benches of newest design and sets of tools. The following electrically driven machines are installed: Five lathes, including a Preston patternmakers lathe, a 12 in. jointer, a 24 in. planer, a 36 in. bandsaw, one universal saw table, one wet tool grinder, one foot mitre machine and one wood trimmer. This is of course one of the main departments and is in constant use. It is in operation every evening in the week as well as Saturday afternoon. The courses are so popular that over 100 applicants had to be carried on a waiting list. The instructors are Messrs. W. S. Mann, head of the department, and Geo. Cole. Besides the millroom students also receive instruction in a large building construction room two stories high, building portable take-down garages, summer cottages, etc., all of which have a ready sale.

The plumbing and steamfitting department is in the capable hands of Messrs. S. Daughtry, chief city plumbing inspector, and Charles Fever. Last year the classes installed a modern five-fixture plumbing installation, some fourteen of the big supply houses donating the equipment and fixtures. Local No. 71, United Association of Plumbers and Steamfitters were so impressed with the good work done that they voted a large donation towards prizes. Another project which was well carried through was the installation of a full steam-fitting system, and much credit was reflected upon instructors and pupils. Both the plumbing and radiation systems referred to are in perfect working order. This season both have been completely dismantled and set up again, affording invaluable practice. The instruction consists of bench work, joint wiping, etc., shop drafting and calculations, etc.

Special provision has been made for instruction in mechanical and architectural drawing. Such drawing is an essential and fundamental qualification in mechanical and structural engineering. It is an indispensable accomplishment in a variety of occupations and often furnishes the key to promotion. This department is in charge of H. F. Ballantyne, B. Ss., and is carried on in a splendid large room, with a northern exposure, giving the best kind of natural illumination. Messrs. H. Etches, M. E., and C. E. Connell carry on large classes in the evenings in mechanical and sheet metal drawing and elementary machine design. Drafting is an obligatory sub-

Automobile Section

ject in the day school and is closely related to the work in the shops.

The science department is located on the second floor, a weighing room and a chemistry room and storerooms. The electrical laboratory contains a demonstrating switchboard of latest type with connection cables, field and charging rheostats, ammeters, voltmeters, etc. In addition there are stationary and portable motor-generator sets, various types of transformers and storage battery system. In fact there is every facility for individual experimentation with high power commercial current machinery. The chemistry room similarly contains, the very latest educational equipment, G. W. Bunton, B. A., specialist in science is in charge. Messrs. F. C. Mace, M. E., and A. B. Lambe, M. E., of the Dominion Power Board have charge of the evening classes in electricity.

The electrical construction shop has all the equipment necessary to give extended instruction in every kind of house installation. A skeleton two-storey, six-roomed house with only rafters and studding showing has been erected in the middle of the shop affording all the necessary practice in the various forms of house wiring. The shop is equipped with benches, etc., and is very busy night and day. The American Bank Note Co. donated the school their discarded telephone switchboard and phones and it is intended to work up instruction in day office installation and maintenance. Instruction in house wiring is in the hands of Mr. J. V. Cummings.

Printing Dept.

The latest department to be opened is that of Printing. This is under the direction of Mr. Wm. Lodge, for years an official in the government printing bureau and a well known labor leader. A splendid trade connection has been worked up and a class of 16 apprentices from outside the school are in daily attendance, besides the regular school classes. It is a model printing shop and splendid work is being done. The equipment cost in the neighborhood of $5,000. It is a matter of local pride that the type cabinets were built by an Ottawa firm, R. A. Sproule & Son, and are quite the equal of anything of the kind produced in America.

Last summer the school was greatly strengthened by the incorporation with it of the commercial department of the Ottawa Collegiate Institute. This enables the management to greatly extend its scope and usefulness and to offer a varied programme of a vocational character. I s aim is to provide a general academic education equal to that of the best high schools while at the same time providing that specialized training now so necessary if our Canadian youths are to be prepared for successful, useful and honored places in life.

Drafting Room

Besides the departments described above, in which the boys and men are specially interested, this article would be far from complete if reference were not made to the most remarkable enrolment of students in the department of home economics and household arts. Thirty class groups meet weekly for instruction in domestic science, 30 more in practical millinery and 50 in plain sewing and dressmaking of the first, second and third years. There are also classes in home nursing, conducted by the superintendent of the Victorian Order, and physical culture under competent instructors. Some 95 are enrolled in the former and 150 in the latter department. To accommodate the great number applying for the above subjects, it was found necessary to open classes at five other centres throughout the city.

Plumbing Shop

The whole system is under the management of the advisory vocational committee of the Ottawa Collegiate Institute Board of which Mr. A. A. Dion, superintendent of the Ottawa Gas and Electric Co., is chairman, and Mr. Cecil Bethune, vice-president of the Board of Trade is the energetic secretary. The other members of the committee are the following, all of whom have taken a very great interest in the cause of vocational education in Ottawa and are to be congratulated upon the success that has attended their indefatigable efforts: G. H. Bowie, who is also chairman of the Ottawa Collegiate Institute Board, J. McKinley, Geo. Patrick, A. E. Provost, J. Raitt, R. A. Sproule, Dr. S. J. McLean, Henry Watters, J. C. O'Connor, Jas. Watson, J. F. H. Laperriere, Allan Fleming. The principal, W. W. Nichol, B. A., who compiled this material, was formerly superintendent of education for returned soldiers under the Ontario Soldiers' Aid Commission, and says he has the able assistance of a staff of some 97 instructors in this most interesting work.

Building garage at Ottawa school

EDUCATION OF YOUTH IS MOST ESSENTIAL

(Continued from page 34)

The Industrial Education Act, under which the Provincial system of vocational schools was inaugurated, was passed in 1911. We have, therefore, reached the end of the first decade in the development of these schools. The growth during this period has been phenomenal. The number of schools has increased from one day school and eight evening schools with an enrolled attendance of 4,000 pupils in 1912 to thirteen day schools and fifty-one evening schools with an attendance of approximately 8,200. The growth has been stimulated by liberal grants for buildings, equipment, and maintenance from the Provincial and Dominion Governments.

The responsibility for taking the initiative in establishing a new school rests with the Continuation School Board, the High School Board, or the Board of Education, as the case may be, of the municipality in which the school is to be estab'ished.

Preparations Being Made for Greater Activity

Steel Corporation Sends Apprentices to School — Instruction Proves Beneficial—Advanced Pupils Study Industrial Work in Local Plants—Parents Interested

By G. W. RUDLEN, B.A.
Principal Sault Ste. Marie High School and Technical Institute

THE SUBJECT of industrial education in the day school for boys has occupied the attention of the High School Board of Sault Ste. Marie for a good many years. In the year 1912 an arrangement was made with the Algoma Steel corporation by which the apprentices in their machine shops should attend the high school on Friday afternoons from 2 p.m. until 5 p.m. at the company's expense, and should study those subjects, which along with the practical work they do in the machine shops, would best fit them for skilled mechanics.

The subjects studied are shop mathematics, machine drawing and elementary metallurgy. Although the boys receive instructions in these subjects for one half day a week, the company has found the plan so satisfactory that it has been continued to the satisfaction of all concerned.

About three years ago the principal of the school and the high school board began to realize that there were a number of boys coming to the school, who were spending a year or so in the first form, and because the subjects leading to matriculation or the teachers' examination did not seem to have any practical value to them, were leaving the high school, going to work in the industries of the city. I am not prepared to say that they were not getting something out of their high school course, because I believe that every boy who comes under the tuition of an enthusiastic and successful teacher of English literature, history, mathematics, and science, and who is induced to faithfully study these subjects in an earnest manner will be benefited. But they were spending a good deal of time on foreign languages, which did not appear to them to be of any practical value, hence they were becoming discouraged, and were leaving school sooner in life than was best for their own interests.

To meet this condition, a class was organized under the day industrial act, and these boys were entered in this course rather than in the regular high school course.

How They Spend Their Time

This is the third year of the experiment, and to-day we have twenty-six boys in these classes, seventeen in the first year, and nine in the second. These classes spend about half of their school time in the wood-working and iron working shops in the high school, and the other half they spend at mathematics, science, English and history. The second year students, this year, have begun to spend part of their time making investigations along various lines outside of the school. The last week in January, the class was divided into three groups, and sent out for an afternoon to make investigations on their own account. One group of three visited the water-works plant of Sault Ste. Marie, Mich., and another group visited the pumping station in our own city.

The third group visited the new court house buildings in the city and studied the heating system. Each group is expected to prepare a report of the visit which is to be presented to the class in a week or two. This programme has two purposes. It teaches the boys that what they are learning at school has a direct application in the industries in their own immediate vicinity, and shows them the application of the principles they are learning. By sending three of them together, and asking for a joint report it encourages them to discuss together what they have seen. Three boys will certainly not agree very long among themselves concerning what has happened in a two hour's visit to a plant, and the fact that they are led to discuss the matter among themselves, may possibly cause them to go back for further information which may be of the utmost value to them.

These classes are not as large in number as one might expect them to be in an industrial centre such as Sault Ste. Marie. The number of boys attending the high school is approximately two hundred, and of these, one in every eight is attending the day industrial classes, and the others are to be found in the regular matriculation courses. The reason for this I have not yet investigated far enough to be able to give a reasoned opinion concerning it.

Question of Opinion

Those who have been following the articles of Mr. A. Pound in the Atlantic Monthly will know that he takes the position that such education is not the best preparation for life spent in our industrial plants where mechanical machinery does so much of the work, and so powerfully regulates the lives of the worker, and that the greatest and best education which prepares him for a proper use of that part of his day which is devoted to leisure, rather than that which is devoted to labor. The report of the industrial education committee in England on the new education, points out the fact that industrial education will only intensify those class distinctions which in a democracy such as ours it should abolish.

We know that as a people we are naturally conservative in our tendencies, and that sudden change from the established order does not appeal to us. It may be for this reason that parents are not in a hurry to send their boys into a course of study which has not been thoroughly tried out, or it may be that somehow they have still somewhere in the back of their heads a feeling that literature and history and even languages are the subjects which will best prepare their boys for the sphere in life to which they hope they may attain.

The day industrial classes in the high school have been doing their work in the manual training department which is equipped with a drawing room, a wood room and a machine shop, and in the physical and chemical laboratories.

General view of machine shop at Saulte Ste. Marie Technical School.

Some of these rooms are not equipped satisfactorily for industrial classes, and so, accepting the grant of the Ontario the Dominion governments, the board decided to build an industrial and technical school in which all vocational training would be taken care of.

New Building

This building is being built at the present time in a location which is more centrally located than the present high school, and will provide accommodation for day industrial, household science, commercial and evening industrial classes.

The building has a frontage of 138 feet and it is 116 feet deep. The walls are of brick and cement, and the floor, mill construction. There are five regular class rooms, an assembly hall which will seat 600 people, chemical and physical laboratories. The household science department has a small home consisting of a living room, kitchen, bathroom and bed-room, with also a cooking and a sewing room. Iron and woodworking are taken care of in a machine shop, motor mechanics room, mill room, bench room and large draughting room.

We have not yet purchased the equipment for this school, but are at present working on it. We hope to open the school in September, 1922 and feel that it will ultimately fill a great need in enabling the school's of Sault Ste. Marie to meet the educational requirements of its future citizens. Following is the material we propose installing in the new school, and the information we regularly request when considering such equipment.

Machine Shop

Principal dimensions of all spindles, bearing sizes, belt widths and other particulars required for intelligent comparison of design of the various machines, must accompany the proposition, and sizes of all pulleys on countershafts and r.p.m. of same must be given for each machine.

One 24-in. metal working planer, single head, vertical and horizontal power feed table not to exceed 6 feet.

Five 12-in. engine lathes compound rests and power cross feed on all. Apron design such that power feed and lead screw cannot be simultaneously engaged. Drip pan preferred.

One lathe with quick change gears, and four without quick change gears, all to have hollow spindle and back gear.

One of the above lathes to be equipped with taper attachment, 6 ft. beds on all machines.

One 12-in. lathe cont. Prefer two different makes in this group of five.

One 16-in lathe, with quick change gear box, 6 foot bed, hollow spindle, drip pan, compound rest and power cross feed, apron design such that power feed and lead screw cannot be simultaneously engaged.

One 20-in. back geared drill, belt driven, upright wheel, lever and power feeds. Vertical adjustment of table only is required but no objection to vertical adjustment of head.

One belt driven sensitive drill, with one swing table, and one table adjustable for height preferred.

One 16-in. stroke belt driven shaper tool head with hand feed, with efficient chuck. Double backed geared.

One full universal milling machine complete with cutter arbor, etc., with dividing head.

Four jaw independent chucks.

Five for the 12-in. lathes, and one for the 16-in. lathes with plates threaded and fitted to the spindles.

One double end bench grinder for approx. 8 x 1 in. wheel.

One power hack saw, improved high-speed type.

20 vises, with parallel jaws, 10 solid, 5 rivol, and 5 adjustable jaws.

Tool Holders

Three straight ½ in. x 1⅛ in. x 6 in., three left hand offset ½ in. x 1⅛ in. x 6 in., and three right hand offset ½ in. x 1¼ in. x 6 in..

We also require several cutting-off tools, knurling tools, lathe dogs, cold chisels, scratch awls, boring tools, tap wrenches, taps and dies, monkey wrenches, stillson wrenches, drill chucks, dividers, calipers, surface gauges, combination squares, try squares, machinists' hammers, punches, steel rules, levels, drill gauges, thickness gauges and thread gauges.

Then we intend purchasing twist drills, countersinks, micrometers, reamers, bolts, sockets, pliers, twist drills, snips, soldering pots, depth gauges, and other kindred equipment.

We also require equipment for the forge shop, and this will include three 90 lb. steel anvils, three anvil blocks, three blacksmith racks, tongs, hardies, porkers, rakes, shovels, hammers, sledges, chisels, punches, etc., etc. In fact all equipment essential to a well conducted forge shop.

Wood-Working Dept.

In the wood-working room we will need the following machines, and in each case the principal dimensions of all spindles, bearing sizes, belt widths and other particulars required for intelligent comparison of design must accompany the proposition. Sizes of all pulleys on countershafts, and r.p.m. of same must also be given.

One 12-in. wood turning, manual training lathe, with outside face plate.

One 16-in. wood turning, manual training lathe.

One horizontal mortiser and relisher.

One swing arm tenoning machine with two coping heads.

One 10-in. buzz planer complete with guard.

One 24-in. pony planer.

One 8-in. four sided moulder.

One 36-in. band saw with full equipment of safety guards.

One universal variety double rip and cross cut saw.

One disc sander with drum.

Two wood trimmers, bench type.

We will also require twenty benches, a variety of planes, chisels, gauges, squares, levels, scales, saws, spoke shaves, hammers, mallets, clamps, scrapers, bradawls, carpenter bits, braces, screwdrivers, dividers, calipers, pliers, nail sets, and other miscellaneous woodworking tools.

In the drawing room we will need benches, tables, boards, instruments, tee squares, triangles, blackboards and similar equipment.

In the motor mechanic dept, we intend installing one complete vulcanizer for various tire sizes, the apparatus to be suitable for technical school instruction.

Four portable vulcanizers for quick road repairs.

One buffing machine.

One 1⅝ in. x 8 in. x 2 in. belt driven air compressor with suitable horizontal receiver equipped with air pressure gauge and safety valve, and three forges with water box.

SCHOOL IS RUN ON MODERN BUSINESS LINES

(Continued from page 42)

will try the examinations set by the department. The printing classes in the evening are composed of printers and printers' apprentices studying advertising design and linotype operation.

Large numbers from the trade attended the class in machine drawing, machine design, architectural drawing and design sheet metal drafting. Young men from the laboratories of various industries in the city attended the class in the fundamentals of chemistry or the advanced work in analytical chemistry.

The evening trade classes are serving a twofold purpose in Hamilton, first, in training workers to perform a more advanced class of work in their trade work, and opportunity to prepare themselves to find employment in a vocation for which they have some interest and aptitude. The value of evening class work, therefore, is to increase the skill of trade workers and to give other workers an opportunity to better their condition. This means much to the industries and to the workers.

All evening courses are definitely outlined and a prescribed amount of work covered in the fall and winter terms. All pupils who complete satisfactorily evening courses are granted certificates. Upon completing all the courses in a department, pupils are granted diplomas.

An interesting booklet has been received from the Kay Mfg. Co. of Norwalk, Conn., which describes the Whiting free floating coupling.

The Canadian Ingersoll-Rand Co., of Sherbrooke, Que., are distributing a new bulletin describing their Price-Rathburn type of oil engine. The booklet is well illustrated with photos and diagrams, showing all the important features of design and construction, also floor layouts for foundations and installation.

Many New Schools Are Being Considered

Vocational Education Surveys Have Been Made Recently—These Bring Out Varied and Valuable Information—Several Schools Now Being Erected—Others Will Follow

THE GROWTH of technical education in Ontario, in fact in Canada, during the past two years has been surprising. However, in the present material, we will confine our data to Ontario, and as Canadian Machinery obtained this information from an official source, it can be considered correct in every detail. There are at present 17 day technical schools in Ontario, and there are 57 centres wherein evening classes are operating.

The equipment used in these schools varies with the size of the school and the number of persons who are accommodated. It would be quite a task to state the number and kind of machines used in each school, but the various articles in the present issue will give readers some idea of the variety of equipment used. During the past two years vocational education surveys have been made in the following centres:— Arnprior, Belleville, Border Cities, Brantford, Chatham, Cobourg, Fort William, Galt, Guelph, Kenora, N. Bay, Oshawa, Owen Sound, Peterborough, Port Hope, St. Catharines, St. Thomas, Timmins and Weston. Since these surveys the following schools have been built, or are in course of erection at the present time:— Border Cities, Fort William, Hamilton, Niagara Falls, Sarnia, Sault Ste. Marie, Sudbury and Toronto.

The following places are considering plans and drawing up specifications with the hope of calling for tenders at an early date:—Kitchener, Guelph, Stamford, St. Catharines and St. Thomas and Renfrew.

Vocational Education

It is interesting to note that the question of providing vocational education has become a matter of serious consideration in each of the places which have asked for a vocational survey. In some of the places wherein surveys have been made it is not expected that this type of education will be provided for some time to come.

The vocational survey which has been made of these places provides such information as the following.—

1.—The types of industry found in the community.

2.—The attitude of the executive heads of these industries towards vocational education.

3.—The classification of employees—male and female.

4.—The classification of adolescents employed in industry.

5.—Courses which would be of assistance in training persons for industry—(a) before employment (b) during employment.

6.—Age, grade, classification of all schools.

7.—Number of adolescents not attending school.

8.—The possible attendance at a vocational school established in the community.

9.—Courses of study which should be organized to meet the vocations of the community.

10.—Accommodation necessary to house these courses of study.

11.—The locality in which the school should be located.

When the survey is completed the school board is provided with a copy of the report which contains not only the above information but the advice of the department of education as to what action should be taken.

The growing attendance in vocational schools which have been opened recently has dispelled any doubts as to the need of this type of education. The adolescent school attendance act is holding boys and girls in school until they have reached their 16th birthday. The greater majority of the boys and girls who left school at 14 years of age entered the industries as industrial workers. It would seem only fitting that these two years which have been added to the school life of these boys and girls should be made to mean as much as possible in knowledge and skill relating to their future occupation in industry.

GOOD WORK BEING ACCOMPLISHED HERE

By J. W. DAY

Principal Public School, Iroquois Falls, Ont.

IROQUOIS Falls, Ont., is very interested in technical education. J. W. Day, principal of the public school in that city sends Canadian Machinery the following information regarding their activities.

We have classes in English (for the non-English speaking), commercial French, electricity, mechanical drafting, mathematics, dress-making, and sewing (for girls).

We have 75 students enrolled in all, and the classes have maintained a good average since the opening in October. The classes are held in the public school on Tuesday and Thursday evenings of each week and continue each evening for two hours.

We have as yet, very little equipment, two sewing machines, drafting boards and drawing sets, drafting tables, tee squares, set squares, etc. We have also a small amount of very good equipment for the classes in electricity which is supplemented by equipment in the mill of the Abitibi Power and Paper Co., of which we have the use. We have been fortunate in securing well qualified and highly trained teachers for the instruction of the various classes, so that we are getting along very satisfactorily.

General view of Iroquois Falls school

CUTTING PRODUCTION TIME IN FOUR

(Continued from page 45)

ling machine tables, and in this case there are three operations, viz, grinding both sides and the top, from each end, of which .020-in must be removed. The tables shown is surface ground complete in one hour including time for handling.

Lathe carriages can also be ground without difficulty, and production time on 14-in carriages, 17-in. wide, ground in the manner shown at Fig. 8, and with .020-in stock removed three sides, is 6 every hour including handling.

Steel racks 4 ft. long, 1⅜-in wide, and ⅞-in thick, for a 14-in. lathe, were ground at the rate of 40 racks per ten-hour day. Four surfaces were ground, each to a limit of .001-in, and removing .020-in. stock from each side. This method reduced planer time 75 per cent., thus effecting considerable saving.

In grinding work of this nature it is impossible to lay down a hard and fast rule for the grain and grade of wheels to be used. The nature of the contact between wheel and work, and the nature of the material makes it practically necessary to experiment a little each time. The one precaution to observe is to be sure and have the wheel soft enough.

Student is Trained to Accept Responsibility

Bi-lingual Instruction Necessary in Montreal School—Separate Staff for Each Section—Age Limit of Fourteen Years for Beginners—Large Attendance at Evening Classes

By IAN McLEISH
Assistant Principal Montreal Technical School

THE MONTREAL Technical School was founded by the government of the province of Quebec and was incorporated by a special Act of Legislature on March 14th, 1907. In September 1911, the first buildings on the present site were opened for day classes, and in October of the same year evening classes were started. The school is bi-lingual and is open to all classes and creeds without distinction. Classes are given in both languages, each section having its own separate staff, so that to all intents and purposes there are two separate schools both using the same buildings and equipment.

The school is built on a lot of ground, over 150,000 sq. ft. in area, and the location is very central being almost equally easy of access from all parts of the city.

On the ground floor the building contains: the administrative offices and waiting room; the museum, where a permanent exhibition of the work done by pupils is displayed; a series of classrooms, forming a quadrangle around the large graded semi-circular amphitheatre which has a seating capacity of 600. On the first floor are located the teachers' rooms, library and classrooms. The second floor is devoted to two large bright drawing rooms.

The chemistry and physics laboratories and lecture theatres are located on the same floor as the basement, but owing to the slope of the land on which the school is built, they really are on the ground floor. Here also are located the locker rooms and dining rooms of the pupils. All the different sections of the main building offer the best conditions from the standpoint of comfort and hygiene. The class rooms are large and well lighted. A ventilation system of purified air provides a pleasant atmosphere at all seasons.

The heating system is through the medium of a forced hot water system, steam turbines producing the required pressure. The water is heated by exhaust steam from engines usually, but if necessary, live steam can be used. A modern electric lighting system is installed. Among the conveniences at the disposal of the pupils is a large waiting room with hygienic toilet rooms and shower baths. The very complete equipment of furniture was built especially for the institution. The apparatus and equipment originally installed has been augmented from time to time by direct purchasing and also by models, patterns, machines, and tools, made by the pupils.

The Mechanics Institute Library, situated in another section of the city, is open to the use of the students.

General view of foundry

The idea that imbues the staff of the school, is that students should not be taught only the elementary practical principles of a trade, but rather, they should be given as thorough and as wide a grasp of the practical problems of the respective branches they are studying as is possible, and in addition they should receive a good grounding in the theoretical and scientific knowledge of this same branch of engineering. The student then has a first class training, which, if he enters a shop as a skilled craftsman, will enable him to discharge his duties creditably from the beginning, and when vacancies higher up occur, he has had the training which, if it has been properly mastered, will permit him to take on added responsibilities. To those students more fortunately situated, a university course follows the technical school training, and it will be found that the duties at the university are considerably lightened, which fact enables them to go further into practical research, scientific reading, and to a fuller extent absorb the benefits of this latter course. Thus this school is not a trade school, but really a technical high school.

Behind the main wing of the building and extending almost to the rear of the lot, are located the workshops and the automobile school. These shops, which are laid out in much the same manner as the shops in industrial concerns, are provided with a complete equipment of modern machinery and resemble the layout of a large general contracting plant. Centrally located is the heating and power plant, which supplies light and power to all the buildings.

The Power House

This department contains two Babcock & Wilcox boilers, equipped with chain grates, and one De Launey-Belleville marine type boiler. The total boiler horsepower is about 500. Here also is installed the steam apparatus for the heating of the entire school. In the engine room there are installed four direct-connected electrical generators. These are:—

A duplex gas engine driving a Canadian General Electric 25 k.w. direct current generator.

A Robb-Armstrong horizontal engine driving a 125 k.w. Allis-Chalmers-Bullock direct current generator.

A compound vertical Bellis-Morcom engine driving a Westinghouse 75 k.w. direct current generator.

A Goldie-McCulough Corliss engine driving a 125 k. w. Allis-Chalmers-Bullock direct current generator.

In this department there is also located the air compressor for the foundry,

storage batteries with a 200 ampere-hour capacity, and the switchboard controlling high and power circuits.

Machine Shop

The area of the machine shop is 11,340 sq. ft. The machines are grouped in three sections, each section being driven by a 15 horse-power motor. A list of the machines is, ten plain 10-inch lathes; twelve screw cutting lathes made by various well known manufacturers, having swings from 12 to 18 inches; one tool room lathe; one geared head lathe; three screw machines, one of which is automatic; four shapers; two planers; one 7 inch slotting machine; nine drilling machines from 10 to 20 inches; one universal milling machine; one plain and one vertical milling machine; one profile milling machine; one pantograph milling machine; one universal grinding machine; one automatic gear cutter; five tool grinders; one buffer; two centering machines; two mandrel presses; a two ton portable crane.

In addition to the above there are the following large machines, each driven by its own electric motor:—six screw cutting lathes with attachments; one three foot radial drill; one horizontal boring mill; one three by four by eight foot planer; and tire lathe swinging 8 feet. The erecting bay is provided with a three-ton electric crane. The tool stores contain a full lin of hand tools, measuring and tracing instruments similar to those used in all modern shops.

The tempering equipment consists of two combination gas furnaces with pyrometers. There are eighty vises and 160 sets of individual tools. In addition to the above, a series of complete machines, including seven lathes, one power saw, one shaper, etc., have been made by the pupils and are now in operation.

The Smithy

The smithy has an area of 5,210 sq. ft. It comprises 24 forges, 24 anvils and one heating furnace. The draft is underground and is produced by a nine horse-power electric fan. A four horse-power electric motor drives a blower which furnishes the blast. The other equipment is a 170 lb. steam hammer, one 75 lb. belt driven hammer, an emery grinder,

View of machine shop looking down center aisle.

a bar shear, a post drill, two swage blocks, two blacksmiths' vises, and one tool bench vise. At the end is located the acetylene welding department, which is fully equipped with modern appartus for twenty students.

Foundry

The area of the foundry is 5,210 sq. ft. The equipment consists of:— one cupola with a capacity of two tons of iron per hour; one oil melting furnace; a combined cupola and a 200 pound crucible furnace. A two ton trolley installation completes the list. An underground installation for compressed air provides for the working of the elevator to the charging platform, and all the pneumatic tools and machines. There are two moulding presses. one core machine; one tenoning machine; one drill; ovens, one sand sifter, one sand mill, one sand mixer, two snagging wheels, one torch heater, and moulders' benches for 24 pupils.

The Woodworking Shop

The machinery of the wood working shop comprises eight belt driven wood lathes, four electric driven lathes of variable speed; one electric hand saw; one cicular saw; one gig saw; one buzz planer; one poney planer; one mortising machine; one tenoning machine; one drill; one shaper; two grindstones; one trimmer; one automatic band saw filing and setting machine; one knife grinder; and one band saw brazer. This shop includes thirty benches with separate sets of small tools for each.

Electrical Shop

The electrical shop of 2,714 sq. ft. area, adjoins the machine shop and thus students can make use of all the tools in

Left hand view shows woodworking department. Right hand view shows smithy room

the latter. The tools located in the electrical shop itself are:—one armature banding and heading machine; one notching press; one shear; one pair of smothing tools; and one buffer. Annexed to the electrical shop is a dynamo laboratory which contains the following machines:—one single phase synchronous motor coupled with a direct current generator; one direct current motor coupled with a three phase alternating current generator; one series wound direct current motor coupled with a shunt wound direct current generator; one rotary convertor; and one direct current motor coupled with an alternator giving single phase, or three phase current, as desired. A specially constructed switch board for experimental purposes provides for the making of any electrical connections or measurements as desired. Located in this shop is testing machine of 15,000 pounds capacity.

Day Courses

Industrial courses extending over three and one half years are provided. These day courses prepare boys and young men for the pursuits of industrial and commercial life. The work of the first year is of a general character. The work of the second and third years is specialized and provides definite training in various trade and callings. It is almost an unbreakable rule that boys under fourteen years of age are not admitted. However, in a very few special cases this rule has been inoperative. Students who can pass successfully an examination in the first year are admitted to the second year. The third year is devoted largely to practical work, fully fifty per cent. of the time being devoted to it.

The evening classes provide scientific and practical training for apprentices, journeymen, foremen, clerks, salesmen, and others who are engaged in industrial or commercial pursuits during the day; and who desire supplementary instruction in the application of science and mathematics to the trades, manufacturing problems, or other pursuits. Each student is permitted to select those subjects which will best help him to make progress in his particular trade or profession. All students are, however, recommended very strongly to precede their scientific courses with a good grounding in mathematics.

The basic idea behind the training in the Montreal Technical School is to train the boys to think for themselves, to use their own initiative. It is not a matter of memorizing a lot of data and formulae, so much as the understanding of the fundamental principles. Boys usually make their own choices as to the branch of studies they follow. The staff of the school assist them directly and indirectly all they can, to get positions or to arrange transfers to better positions. Full sized work is now standard practice as in some instances such product can be disposed of for sums that equal at least the cost of the raw materials.

Large Addition to School May Be Constructed Soon

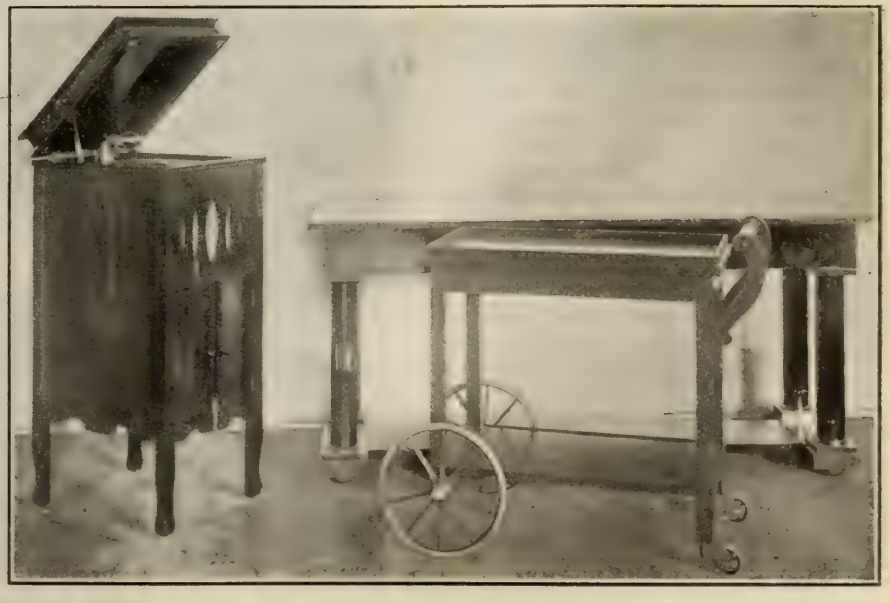
By A. P. GUNDRY, B.A. Principal Collegiate Institute, Galt

TECHNICAL education is not being forgotten in Galt, although at present there is no machine shop section. Speaking to A. P. Gundy, principal of the Collegiate Institute, Galt, Canadian Machinery discussed present activities and future possibilities. Following is the result of the interview:—

Classes in shop mathematics are held, about 35 to 40 students attending. Some of the boys are further advanced than others and owing to this fact, no hard and fast rule of tuition is adopted. One might be studying long division, while another might be delving into problems in trigonometry. As much as possible the students are classified according to the extent of their previous knowledge of mathematics.

There is also a class of about 35 to 40 in mechanical drawing. Usually the students come from the apprentices in the various factories in Galt, thus adding to their mechanical knowledge. A three year course is adopted, and successful students receive a diploma at the end of each year. The classes run from October to April, and two nights every week are set aside for study.

The wood working department is devoted chiefly to cabinet and pattern making. Usually about twenty students attend, and the equipment consists of two wood lathes, one surfacer, one band saw and a C. M. C. variety saw with mortiser attachment.



Classes have been held in automobile mechanics, although there is none this year. Prospects are bright however for a continuation of this subject. There is also a fifteen-week course in electricity, and about 20 students attend. This year, house wiring is being studied.

Then there is the regular day manual training classes, commercial work, home nursing, household science, etc., etc., but as the latter mentioned are not of special interest to readers we will not dwell on their activities.

The illustration shown with this article gives some idea of the class of cabinet and general woodwork being done by the students. These are only a few of many articles completed.

At present things are very congested. There is no space for many needed classes, and there is a strong possibility that a new wing will be added to the present school. In fact as time goes on, it is hoped that two wings will be built, as there is considerable ground surrounding the present site. The board are studying the problem of plans at present, and if this goes through satisfactorily, the first three floors will be devoted to industrial purposes, and the fourth to commercial classes. Mr. Gundry is an enthusiast, and there is no reason why Galt will not be able to do big things for technical education in the near future.

Tenders are being called for by the Guelph Board of Education for a new collegiate institute and vocational school combined, estimated to cost in the neighborhood of $320,000. The Department of Education will bear its share of the portion of the building devoted to vocational purposes. It will be erected on the present collegiate campus and besides supplying adequate class room for the overcrowded collegiate, which has been repeatedly scored by high school inspectors, will supply workshops for woodworking, machinery, motor mechanics as well as quarters for manual training, commercial work, etc.

Examples of Woodwork turned out by Galt Students

A Boy Must be Able to Use His Hands and Brain

Students Are Taught That the Fundamental Principles Must be Mastered Before Further Progress in Practical Work Can be Made—Ideas Regarding the Type of Equipment Necessary

By L. BISCAYART
Principal Three Rivers Technical School

THE THREE Rivers Technical School was opened September 18, 1920, and has been in operation since that time. Day c asses are planned for the boys who went through grammar school and who wish to acquire the technical knowledge, as well as the manual skill required for the formation of capable workmen, prospective foremen and superintendents.

The following trades are dealt with: joinery and pattern making, foundry, forging, machine work, tool making, and draughting. The instruction given is both theoretical and practical. The theoretical instruction has always a technical character and consists mainly in the study of arithmetic, algebra, geometry, trigonometry, physics, chemistry, applied mechanics, mechanical drawing, construction, technology, etc.

Practical instruction is given in four shops, namely the wood working shop, the foundry, the machine shop, and forge dept. During the first year, pupils are not specialized but spend a few months in each shop. These stages develop their manual skill and enable them to select with more certainty, the trade to which their talent or ability seems to be best fitted.

At the beginning of the second year, students select the trade they intend to learn, and devote all their time to that specialty until they graduate, at the end of the third year.

Wood Working Shop Equipment

The wood working machines actually installed are of standard make and include:—

Five high speed Blount lathes; one high speed Blount lathe with outer face plate for turning large diameters; one universal Crescent woodworker that is a compact combination of band saw, rip and cross cut saw table, boss planer, shaper, mortising machine, sand papering disc machine, grinder, borer, etc.

One pony planer that can handle material 24 in. wide by 8 in. thick; a dowel pin cutting machine; a saw filing machine; a saw setting machine; and a wet grindstone of large size.

The lathes, grindstone, dowel machine, saw filing and setting machine are driven by a 5 h.p. three phase induction motor. The universal woodworker has its own 5 h.p. motor. The pony planer is driven by a 10 h.p motor, and any further equipment installed will derive its power from this motor. The shop is equipped with eighteen stoutly built hardwood carpenter benches with grip and vise, with several drawers for the safe keeping of hand tools.

Each student is supplied with a cross cut and a rip saw, an 18 in. plane, a 14 in. plane, a jack plane, chisels of various size, divider, try square, gauges, wood turning chisels, mallet, etc. Step by step pupils are taught the use of all their tools. This is done by selecting exercises in which difficulties increase gradually. After having gone through about twenty-five exercises a student is able to plane, square, true up his work, to make tenon and mortise assemblies, dove-tails, framing, paneling and this at varying angles.

Special tools such as mitre box saws of Stanley make, Oliver wood trimmer, planes of all description, wood carving tools are available although not distributed to students as individual tools. An electric glue heater, a small veneer press, clamps of various description complete the wood working equipment.

Special students and night students that had previous experience, are trained in pattern making, carpenter work, stair building, etc. These are made at a reduced scale, but the same difficulties are to be found in their execution as if made full size.

The foundry has a cupola of Whitney make that can handle 500 lbs. of metal, a core oven, the necessary flasks, copes and molding tools to train twenty-four students on bench work.

Blacksmith Shop

This shop is equipped with eight Sturtevant underdraft forges, and as many anvils, one swage block, a 75 lb. belt driven hammer, and all necessary hand tools. A suction fan and a blower, built on a platform, are driven by a 10 h.p. motor.

Below this platform we have installed a Stewart oven furnace and a barium chloride furnace with the necessary fuel oil burning equipment, which is mainly a pressure blower driven by a 3 h.p. motor. Heat measurements are made with a pyroscope, one of the latest optical applications of photometry to the measure of high temperatures. In the forge are located five complete oxy-acetylene welding outfits of commercial size.

Machine Shop

The machine shop is equipped with the following:

Six South Bend 13 in. lathes; four

Views of heat treating department, automobile department, stair making and general wood working sections

South Bend 16 in. lathes; one Seneca Falls 16 in. lathe with backing and relieving attachment, tapering attachment, automatic gear shifting; one Preston 18 in. lathe; one universal turret lathe; one Rhodes slotter; one Rhodes shaper; two Whipp 16 in. shapers; one centering machine; one Springfield wet emery grinder; one Williams double head dry tool grinder; one wet stone grinder; one Greenfield universal grinder with internal grinding attachment and one Dumore tool post grinder.

One Bertram planer; one Racine high speed power saw; one Hendey universal milling machine with dividing head and all attachments for vertical milling.

The individual equipment includes, besides cold and cope chisels, files, hammers, punches, hack saws, dies and taps, reamers and drills. solid work benches with thirty-eight parallel vises. Needless to say such equipment can be used to make practically anything that can be turned, milled, shaped, planed, bored, or ground.

Students are first trained to chisel and file. This work is rather irksome to beginners, but we strongly believe that a mechanic, in the true sense of the word, should be able to use his hands skilfully, and nothing will reach that aim as well as filing. The various exercises are so designed as to increase the difficulty of the work, to match the rising skill of the pupils.

It requires a long training before a student is able to file and scrape a true surface and to make its sides square to dimensions. This is the "touch stone" by which we can gauge the mechanical instincts of our students. Those who understand our aim, will go doggedly through the hand blistering and tedious process of filing and make a success of it.

We want students to realize that before a boy can run, he must learn to walk, before he learns to write he must know his alphabet, and before he becomes a machinist he must know how to use his hands and his brain skilfully.

The machine shop has the use of the oil burning hardening oven furnace and barium chloride furnace for tool work, but for tempering smaller tools, we are equipping an electric muffle furnace of 3 k.w., that can handle all but the larger pieces and heat them to 1900 F., which is quite sufficient for all carbon steel tools. The pyroscope is also used for reading and controlling the temperature of this furnace.

Drafting Room

The drafting room is quite large, and can accommodate forty students without crowding. A Buckeye vertical arc printing machine is part of the equipment of this department. The physical and chemical laboratories are scarcely equipped, but all the instruments required to illustrate the fundamental principles have been selected. The same applies to the electrical laboratory.

Night classes are given in the automobile section. This includes one four cylinder, and a Ford chassis, in running order, a Pope four cylinder chassis, a Saxon six cylinder chassis. We also have two four cylinder engines, one large six cylinder Mitchel engine, a six cylinder Russell Knight engine, one eight cylinder Regal engine, one twelve cylinder engine, one single cylinder stationary engine, one 4 h.p. two-cycle marine engine, one 3 h.p. motor cycle engine, and a collection of dynamos, magnetos, carburetors, starters, coils of various description. This department will be improved with our financial condition.

Showing Machine Shop, forge and foundry of Three Rivers Technical School

Our stationary engineers' department is in an embryonic condition and includes for the present one vertical tubular 10 h.p. boiler, one 8 h.p. compound marine engine, one 2 h.p. horizontal engine, and one duplex feed water pump, one ¼ h.p. steam turbine.

Now we might draw a few conclusions from our experience in installing and equipping shops for industrial and technical schools. We will find people that will emit contradictory opinion with very good faith and great experience, but our conclusions might find favor with others, as they are based on sound common sense.

Some educators believe that a machine shop should be equipped with as many different types of lathes as possible, to give a chance to the student to vary his experience and to run any make of machine. The idea is a good one, and we accept it, but its realization is expensive for a school, and breakage will condemn a machine to idleness unless a stock of parts is carried for each one of them. By purchasing one type of lathe or perhaps two, spare parts required are fewer, and being interchangeable will make replacements a simple affair. We believe that working on one type of lathe, or on another is very much like driving different cars. An expert mechanic will not be long before he learns the secret of the automatic gear shifts, if he knows how to compound his gearing on the simpler lathe.

We have a universal woodworking machine that is giving us excellent service. It is well designed, well built, and while we do not intend to throw discredit to its makers, we feel that in a school where space is not an object, separate units are preferable. The reason is quite obvious. Woodworking machines are dangerous if carelessly operated. It is hard to watch a class of youngsters clustered around a universal machine, when the proximity of workers might cause accidents due to distraction, playfulness or carelessness. Besides, wood shavings and saw dust are thrown in between the frames, which make it hard to keep this type of machine as clean as school requirements demand. At the end of each period, the shops must be left in such a condition, that the next class will not be induced to leave them dirty.

(Continued on page 61.)

These Pupils are Classified in Order of Merit

Three Year Course—Examinations Three Times a Year—Tools and Materials Supplied by School—Registration Fees Paid in Advance—Skilled Mechanics Being Developed

By W. VAILLANCOURT
Principal Quebec Technical School.

THE QUEBEC Technical School was founded by the Government of the Province of Quebec and incorporated in March 1907. The present buildings were opened for day classes in September 1911 and for evening classes in October of the same year. The school is under the management of a board of directors whose appointments are indicated below:

Art. Picard, chairman; J. A. Marier, secretary-treasurer; G. E. Tanguay, and Hon. Frank Carrel, appointed by the Provincial Government; J. A. Lesage and Dr. V. Martin, appointed by the City of Quebec; J. H. Fortier, appointed by Board of Trade; Art. Paquet, M.P.P., by Provincial Government as Labor representative, and W. Vaillancourt, principal.

The teaching staff consists of the principal and the following professors: J. A. Buteau, B.S.A., C.E., mathematics and mechanics; J. R. A. Desy, drawing; M. Koetz, B.S.A., Ch. E., physics and chemistry; J. Thomas, mathematics; A. V. Dumas, El. Ch. E., mathematics, electricity and industrial technology. Shop work is carried on under the following instructors: M. Giauque, machine-shop; Jos. Gillaume, foundry; J. Halle, woodworking; A. Rousseau, smithy.

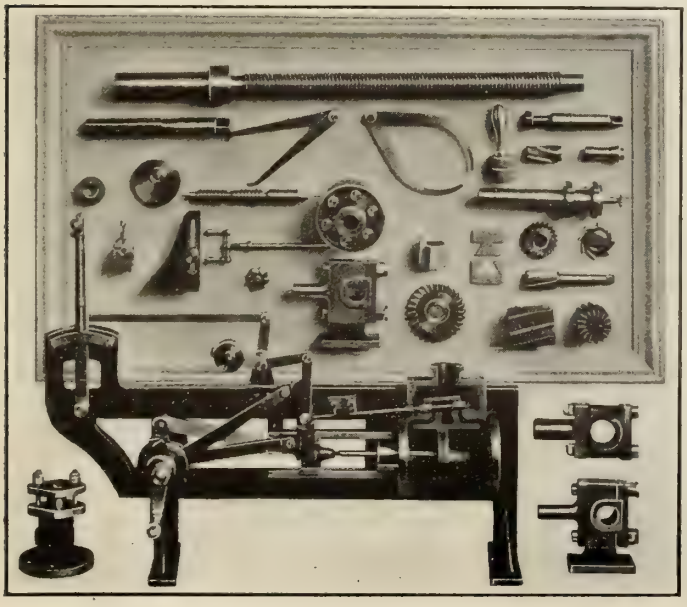
The Quebec Technical School is built on a lot of ground over 100,000 sq. ft. in area. The main building, 250 ft. x 50ft. contains the administration offices, the museum, the library, the class rooms, the laboratories, the locker rooms, the toilet rooms and an assembly hall.

The boiler-room contains two 100 h.p. Jenkes boilers and the heating force hot-water system apparatus. The engine-room contains three electrical groups with direct connections, viz:— 1. A 90 h.p. compound vertical Bellis-Morcom engine, direct connected to a D. C. generator. 2. A 35 h.p. Robb Armstrong horizontal engine direct connected to a D. C. generator. 3. A 30 k.w. motor generator set connected to the Quebec R. L. & P. Co. line. Since 1915, on account of the large demand on the coal market, our steam engines have operated only when the heating of the building can absorb the exhaust steam.

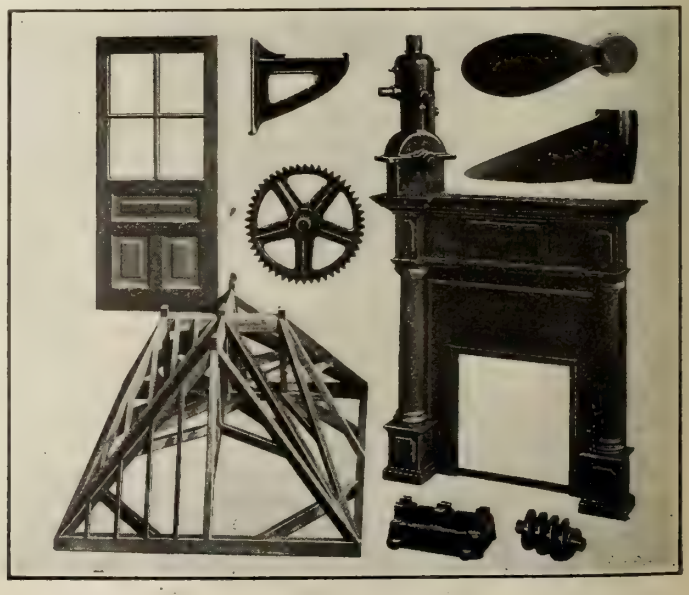
The machine shop has an area of 3,100 sq. ft. and contains the following machines: 16 lathes of different makes, 1 boring mill, 1 milling machine, 1 universal milling machine, 2 shapers, 1 slotting machine, 1 planer, 4 drills, 4 tool grinders, 1 centering machine, 1 mechanical saw, 1 mandrel. This equipment is installed on the group and motor drive principle. 1 Stewart gas furnace with an electric pyrometer is used for hardening and cementation of tools. 36 vises and 72 sets of individual tools complete the equipment.

The smithy has an area of 1,488 sq. ft. and is provided with 10 down draft Buffalo forges. An 18 h.p. electric motor is used to drive the blower, the fan and a 75 lb. hammer. One swage block, one blacksmith vise and one tool bench vise complete the equipment.

The foundry, having an area of 1488 sq. ft., is provided with one Whiting cupola of 1½ tons per hour; one 100 lb. crucible furnace, one molding press, one core machine, one sand mixer and 12 molders' benches.



The wood-working shop has a floor area of 3100 sq. ft. and contains: 1 circular saw, 1 band saw, 1 jointer, 1 planer, 1 chain mortising machine, 1 tenoning machine, 1 boring machine, 1 shaper machine, 2 grind-stones, 1 automatic band saw filing and setting machine, 1 knife grinder, 6 wood lathes. These machines are of underground groups and motor drives. This shop includes 20 benches with 2 separate sets of tools each.



A two-story garage has just been erected with 6500 sq. ft. floor area and will be open soon as an auto school.

Day Courses

The day courses are organized for the benefit of young men who, having recently finished their elementary studies, are anxious to acquire the technical training and the manual proficiency necessary to become skilled mechanics, capable foremen or shop superintendents. These courses prepare for the following callings: pattern-maker, joiner, moulder, machinist, blacksmith, electrician, draughtsman.

The instruction is both theoretical and practical. The theoretical instruction is always of a technical nature and comprises the following subjects: arithmetic, algebra, geometry, trigonometry, physics, chemistry, electricity, general and applied mechanics, technical draw-

Showing samples of work constructed by students

ing, and industrial technology. Practical instruction is given in the following shops: wood-working department, foundry, smithy, machine-shop. These shops are provided with the best of material and equipment.

During the first year, students do not specialize; they spend four successive periods of about two months and a half in the machine-shop, smithy, foundry and wood-working department, in order to acquire the elementary technical points connected with each particular trade and to be in a position at the beginning of the second year, to specialize in one of the above shops. Draughtsmen specialize in the fourth year only, if graduated as machinist or pattern maker. Electricians specialize in the fourth year only, if graduated as machinist.

The day courses are given in the two languages. This is found necessary owing to the dual characteristics of the people in the Province of Quebec, and students, therefore, are divided into two distinct groups: the English section and the French section, according to their choice. Both sections however, are united for the drawing lessons and shop work. Home work comprises about 4 exercises per week.

To be admitted to the Quebec Technical School, candidates must pass an easy written examination on subjects selected from the programme of studies of the elementary schools. Applicants should be at least 14 years old. No one is admitted unless he has given satisfactory proofs as to morality, age, intellectual and physical fitness required by the regulations. The school keeps no boarders. Non-resident students must board in private families. A room is provided for boys who wish to bring their noon lunch to school.

The school is in session from the beginning of September to the end of June. It takes three years to go through the full course. No student may pass from one grade to the following one unless he has obtained the minimum number of obligatory marks. An examination is held three times during the year; and, as a result, pupils are classified in order of merit. A report giving the details of the standing is then mailed to the parents.

Official diplomas are awarded by the board of directors to students who pass a satisfactory examination at the end of their studies. The diploma specifies the course followed.

Tuition fees are fixed at $15.00 per annum for the first year, $40.00 for the second year, and $50.00 for the third year. They are payable in advance in ten equal instalments on the first of each month.

Copy-books, drawing materials, etc., are at the pupil's expense and may be bought at the school. Text books are furnished by the school; they may be purchased or hired; in the latter case, the charge is $1.00 per annum. Students should also be supplied with overalls for shop work. The school supplies free of charge all tools and material necessary to carry on practical work. Students are liable for the equipment in their possession. The school will not hold itself repsonsible for articles provided to students or belonging to them. A deposit of $2.00 is required of each student to cover breakage and loss of material. That deposit is not returned to students leaving the school during the year.

To receive full benefit of a shop technical education, the boys should be at least 16 years old and have completed their seventh year in the public schools. With such students, the weekly schedule could be as follows:

Subjects Taught	1st Yr. hrs.	2nd Yr. hrs.	3rd Yr. hrs.
Shop Work	24.	24.	32.
Industrial Drawing	6.	6.	6.
Technology	1.5	1.5	1.5
Mechanics	1.5	1.5	1.
Geometry	1.5	1.5	1.
Arithmetic	1.5	...	...
Algebra	1.5	1.5	1.
Physics	1.5	1.5	..
Chemistry	1.5	1.5	...
Electricity	...	1.5	1.5
Moral	.5	.5	.5
Totals	41.0	41.0	44.5

Scholarships covering the whole or part of tuition fees may be awarded by the directors to good students of first and second years when their family is deserving assistance. Scholarships are granted for one year only. They may be reduced or withdrawn entirely should circumstances warrant.

Evening Courses

The object of the evening courses is to give to workmen and apprentices theoretical and practical instruction to help them in the practice of their trades. Any applicant over 14 years of age and who possessses an elementary education is eligible for admission to the night courses. Fees are payable in full at the time of registration. A personal identification card is delivered to each student. Said card is to be shown when requested. No refund of tuition fee is made to any student who may leave during the term. Certificates are granted each year to pupils who successfully pass the final examinations or whose work, during the session, proves to be satisfactory.

Following is a schedule of the various courses:

Joiners:—Wednesday and Thursday, 7.30 to 9.30, 40 lessons, $6.00.

Pattern-Makers:— Wednesday and Thursday, 7.30 to 9.30, 40 lessons, $6.00.

Mechanics:—Beginners: Tuesday and Friday, 7.30 to 9.30; Trained pupils: Wednesday and Thursday, 7.30 to 9.30, 40 lessons, $8.00.

Blacksmiths:—Wednesday and Friday, 7.30 to 9.30, 40 lessons, $6.00.

Founders and Moulders:—Tuesday and Wednesday, 7.30 to 9.30, 40 lessons, $6.00

Firemen:—12 practical lessons: Friday, 7.30 to 9.30, 10 theoretical lessons: Wednesday, 8 to 9.30, 22 lessons, $5.00.

Stationary Engineer:—18 theoretical lessons: Tuesday, 8 to 9.30, 15 practical lessons: Thursday, 7.30 to 9.30, 33 lessons, $6.00.

The above two courses for firemen and engineers are organized in view of the examination to obtain a license.

Electricians:—15 practical lessons (wiring): Friday, 7.30 to 9.30, 30 theore-

Showing forge and machine shop

tical lessons: Wednesday, 8 to 9.30, 45 lessons, $8.00.

Mechanical Drawing:—Tuesday and Friday, 7.30 to 9.30, 40 lessons, $6.00.

Architecture, Drawing and Building Construction:—Tuesday and Friday, 7.30 to 9.30, 40 lessons, $6.00.

Automobile Chauffeurs:—Thursday, 8 to 9.30, 20 lessons, $8.00.

Applied Mechanics:—Monday and Friday, 8 to 9.30, 30 lessons, $6.00.

Ideal Machine Shop

To receive full benefit of a shop technical education, the boys should be at least 16 years old and have completed their seventh year in the public schools. With such students, the weekly schedule could be as follows:

	1st Year hrs.	2nd Year hrs.	3rd Year hrs.
Shop Work	17.5	20.	23.5
Industrial Drawing	6.	6.	6.
Technology	1.5	1.5	1.5
Mechanics	1.5	1.5	1.5
Geometry	1.5	1.5	1.5
Arithmetic	3.	1.5	1.5
Algebra	1.5	1.5	1.5
Physics	1.5	1.5	...
Chemistry	...	1.5	1.5
Electricity	...	1.5	1.5
Language	1.5	...	...
Moral	.5	.5	.5
Total	36.	38.5	40.5

Shop hours for the three years will amount to 3200 hours with 40 weeks in the school, or 400 8 hr. days (1 1-3 year.) One half of the first year machine shop time will be devoted to bench work and one fifth of that of the 2nd and 3rd years. For 100 students: 1st year 50; 2nd year 30; 3rd year 20; the machine shop should be provided with 100 individual sets of small tools: calipers, squares, chisels, hammer, files, vises' jaws (copper and lead), surface gage, punch. 50 bench vises, 3 emery wheels, 2 mandrel presses, 1 mechanical saw, 2 centering machines, 1 universal grinding machine, 2 universal milling machines, 1 vertical milling machine, 6 drills from 10 inch to 20 inch, 2 slotting machines, 1 planer, 5 shapers, 2 screw machines, 8 plain 10 inch lathes, 14 screw cutting lathes, 1 radial drill, 1 vertical boring machine, 1 horizontal boring machine.

If there is no smithy department the following should be added to the machine shop: 2 forges complete, 2 furnaces for tempering with baths, 2 welding outfits. Machine tools should be provided with attachments, at least some of each type. The tool store should be provided with all the modern tools used in the best shops.

The wood-working shop should be provided for 100 students with 100 individual sets of tools: chisels, try squares, bevels, gauges, tenon-saw, black plane, mallet, hammer, 75 joiner benches, 2 band saws, 1 automatic band saw and filing and setting machine, 2 combination saw tables, 2 shapers, 2 jointers, 1 knife grinder, 1 planer, 1 planer and matcher, 1 swing cut-off saw, 2 universal borers, 1 tenoning machine, 1 mortising machine, 20 lathes, 2 grinding wheels.

The pattern shop should be provided with a few moulders' outfits.

Students Bring Difficulties to School For Consideration

By J. DAVIES
Instructor in Shop Mathematics at Oshawa

OSHAWA evening schools commenced operations in the fall of 1919. The first machine shop practice class was held in the basement of the public library. The following year the class was held in the King Street school the accommodations being much better.

This year we have an enrollment of 18 in the class, and the ages of the students vary from 15 to 35. The majority are working at some branch of the machinist trade in Oshawa. We carry out the work as closely as possible to the following syllabus:—

1.—Measuring tools and how to use them—rule scale, micrometer, vernier, indicators. 2.—Tools usually found in machinist's tool kit—squares, combinations, bevels, protractors, calipers, etc. How to handle and test for accuracy. 3.—Drilling machine work. Setting up and holding all kinds of jobs—practical examples taken from the shop. How to select, use and grind— drills, cutters, reamers, boring bar tools, etc., feed and speeds with arithmetic for calculating same and time required for different jobs. 4.—Lathe work—centering, straightening and driving the work, thread cutting, turning cams, tapers, face plate and chuck work. Fractions, decimals, ratio and proportion will be taught in order to make the necessary calculations for thread cutting and taper work, etc., with many practical examples of running fits, drive fits, force fits and shrink fits. 5.—Milling machine work, gear cutting, plain, taper and spiral reamers and cutters. How to use the dividing head for spacing—calculate change wheels for gear cutting with the different angular calculations required to set different classes of work. 6.—Grinding on universal grinder, laying off and making templates bench work, shaper and planer work. The elements and application to workshop problems of trigonometry as far as the time and the progress of the class will permit. The class meets twice a week from 7.30 to 9.30 p.m.

We make the class as interesting as possible. Various tools, jigs, and machine parts are borrowed from local factories and the students are asked to describe how they would perform the various operations involved, care being taken to select some tool or operation which involves some mathematical calculation.

The students are also invited to bring any of their shop difficulties to school for consideration. Sometimes the programme is varied by asking them to write out in detail how a certain piece of work should be performed, with a description of tools and jigs required. The time required, with the probable cost of production is calculated and by this means we get quite a number of original ideas. Each of these ideas are carefully examined and without mentioning any names, the merits and demerits of proposed methods are freely discussed.

One of the greatest difficulties in a class of this kind, is the time it takes to teach the fundamentals of arithmetic before they can be applied to practical work. Some of the students are much more advanced than others, but the students show a fine spirit of co-operation and are willing to help each other and give and take a little.

The principal, Mr. A. E. Garbutt, and the board of education are doing all that is possible to make these classes a success.

Orillia school. Article appears on page 43.

Taught to Select Best Machine for Purpose

By J. D. DICKSON, B.A.
Principal Collegiate Institute, Niagara Falls

THE Niagara Falls Technical school which, with the present equipment, cost about $230,000.00 and was completed over a year ago. It contains a well equipped woodworking room, a fully equipped machine shop, an up-to-date household science room, with an electric range, electric ovens and twenty-two electric plates for the students, a dressmaking room, a draughting room, a typewriting room, three large class rooms and three laboratories viz. physical, chemical and electrical.

The day classes are provided with a three years' course in commercial work, technical work for boys, and homemakers' course for girls.

The evening classes have a wider range with less academic and more practical work. There are classes in all commercial departments, salesmanship, English, mathematics, cooking, dressmaking, millinery, mechanical and architectual drawing, woodworking, machine shop practice, oxy-acetyline gas welding, electro-plating and practical courses in electricity.

The woodworking room is 60 ft. x 32 ft. and the machinery in it consists of a circular variety saw, a band saw, a pony planer, a jointer, a hollow chisel mortiser, and three wood turning lathes all of which are run by individual motors except the lathes which are run on a line shaft.

These machines are arranged across the ends and down one side and the twenty-one work benches with a full set of tools for each fill up the rest of the room. The photograph shows how the machines and benches are arranged.

Methods of Tuition

In the woodworking room a student must learn to know the name of each tool, what kind of work it is best fitted to do, and how to use it. This takes some time. A good deal of practice in the use of tools takes place before one is allowed to use the machines. Further, a progressive system of mechanical and geometrical drawing has been co-related with his practical work from the very beginning.

In using the machines the same order is allowed viz. the name, its use, and how to use it. It requires a good deal of training and experience on the part of a student to select, in every case, the best tool or the right machine for doing a certain piece of work. The work in drawing is continued up to the point where the student can at least make and interpret ordinary blue prints.

The machine shop is 45 ft. x 32 ft. and is equipped with three lathes, two of them C. M. C. 16 in x 6 ft., and one a Walcott 14 in. x 6 ft., one Brown and Sharpe No. 2 universal milling machine, one No. 6 perfect grinder for tool grinding, one Champion drill press, one No. 4 arbor press, one Racine 6 in. high speed saw, one Globe universal tool and cutter grinder, one 16 in C.M.C. Shaper, one small hand forge with anvil, sledge and tongs and a bench eighteen feet long on which are placed five vises.

The motor which drives all these machines is a Crocker-Wheeler 7½ h.p. which runs at a speed of 750 r.p.m. Each machine is belt driven and the speed of the line shaft is 220 r.p.m.. The line shaft, 1 15-16 in. in diameter and 18 feet long, is supported by four hangers with S. K. F. ball bearings.

An outline of the course to be followed in the machine shop has been worked out and carefully arranged by the department of education and this has been found to be of the greatest service for the guidance of the teacher. It would be neither interesting nor profitable to list the apparatus in the different laboratories further than to say that the equipment in the electrical laboratory is considered to be the best that can be procured. Canadian Machinery has had an opportunity of looking over several of the drawings made by students in this school, and they are very well prepared indeed.

BOY MUST BE ABLE TO USE HIS HANDS

(Continued from page 57.)

Individual drive, for machines, has many points to its advantage in factories where production is the first aim. In a school the problem is not the same. We prefer to use small motors say 5 h.p. driving a few machines to its full capacity. This is more efficient, electrically, than the single unit that is not always working at full load. It is quite simple, and belt drive can stand more punishment and abuse than any other form of transmission without ill results. Machines should be arranged in such a way as to group them together so as to avoid running a motor for one machine only, for any length of time.

We feel that the time has come to make an appeal to manufacturers regarding our schools. We beg their indulgence for the youths that come out of them, their heads swollen with hopes and self-confidence, believing they "know it all."

Give them a chance to learn to work the way you want by applying what they have learned. Their first attempt may not prove a success, but the material for quick improvement has been drilled into them. They are like well trained soldiers who have not been to war. It takes time to turn the best soldiers into a mature veteran. Do not condemn technical education on the ground that the boys are not taught what they need, and remember your own past experience. You had to start at the bottom, struggle along the best you could, and find sometimes that you were handicapped for the lack of knowledge along some particular lines of your work.

Technical education, cannot turn out a ready-made perfect product. We aim to teach our students "to learn" to walk in life by showing them their first steps.

General view of woodworking department in Niagara Falls School

Practical Ideas for Shop Executives

HOW TO MAKE YOUR OWN ALUMINUM CASTINGS

By D. A. Hampson

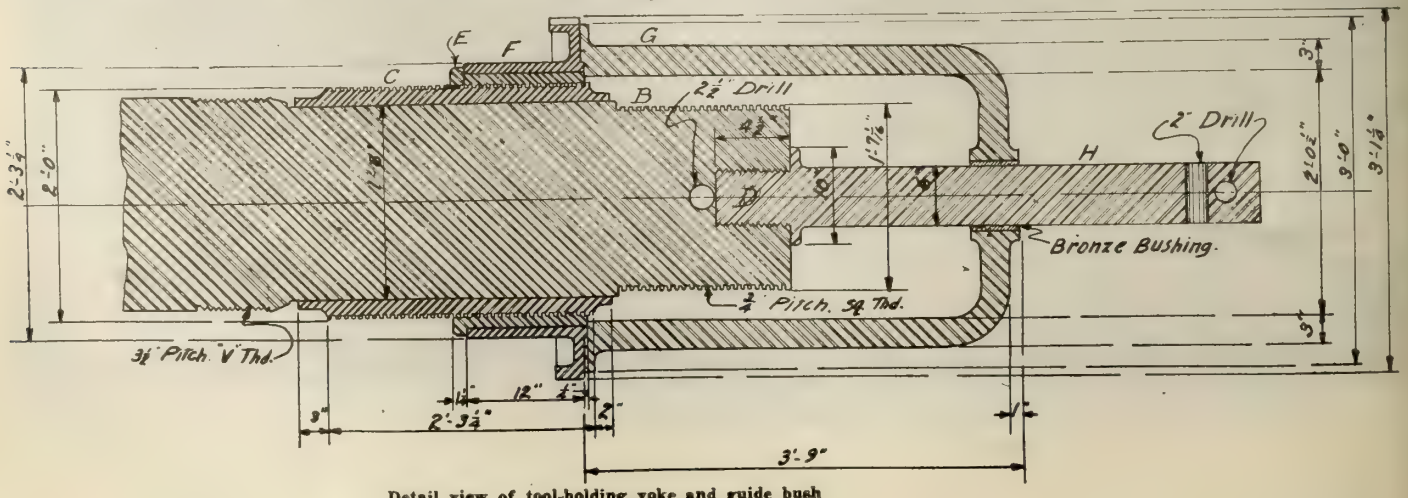
The title does not imply that every shop ought to do that as standard practice but its purpose is to describe how any shop at a remote distance from an aluminum foundry or any small iron foundry may do this thing in emergencies. Not that such action has been impossible before but the average routine mind would put the job in the specialist's class.

Suppose a small casting is wanted in a hurry, or an aluminum pattern, or set of patterns for a gate is required for the foundry. If there is enough aluminum available and some sand, even though it be not molding sand, it is possible for the mechanic to get along with the job. Of course, a job of cored work or an intricate shape would be beyond the ability of anyone not a molder or, at least, with a thorough knowledge of molding practice. But the work we have in mind has one face nearly flat and the draft all one way, as a half pattern for a small iron pulley or a pattern for a pipe flange.

Having prepared the sand, a flask must be secured, and this may be an ordinary box into which the sand is dumped; the writer has seen larger castings made this way by bedding them in the floor, the "floor" being a pit dug out in the yard into which the sand was shovelled, and the furnace being a portable forge. Having prepared the mold, the aluminum scrap is heated in a cast iron babitt ladle in whatever means is available—a forge or furnace, as the case may be. Aluminum melts at 1,200 degrees F. and cast iron at 2,300 degrees, so there is little danger of injuring the ladle—hardly more so than with some babbitts. If the job was done in a foundry, heating would be done in one of the braziers used to warm the place and the fire would be of coke. A blacksmith's fire will do in other cases. As with all pouring, the furnace should be near the work and the workman should wear goggles—the latter being especially important in the case of an amateur.

The resultant casting may not be a work of art nor will it have been scientifically mixed but it fills the bill—and who can deny that good practice is anything else? In numerous cases, this method has supplied needed parts in two hours that otherwise would have entailed a week's delay. The writer has tried to have some molding sand about the shop at all times for the above purpose and for lead castings and for pattern makers' use. There are instances where a lead casting is wanted from an existing pattern; a box about 18 in. x 24 in. x 12 in. deep filled with sand answers the requirements for this work. Then, too, it is educational for a patternmaker to stick a pattern in the sand and try to draw it—he acquires respect for the molder then and there, and his patterns will be more workable from that minute. A little time spent in making a mold and placing a sand core therein will often show that the design is not what was intended and that alterations are necessary.

CUTTING LARGE THREAD



By G. F. Roberts

How would you cut a square thread on the end of a large shaft weighing approximately 25 tons? This was the proposition we ran up against a short time ago, and needless to state, we soon made up our mind that this was no ordinary lathe job. The shaft was 29¾ dia. at the largest point, and was 23 ft. 2 in. length over all. The thread required was ⅜ in. pitch for a distance of 18 inches.

We decided something special in the nature of threading apparatus was necessary, and luckily the construction of the shaft helped us out in this repect. Readers should refer to both Figs. 1 and 2 from time to time when following this description, but special attention is directed to Fig. 2, which shows the detailed sectional view.

Considering Fig. 2, we note a shaft or support H screwed into a central threaded hole O. Luckily this hole was already in the shaft, so all we had to do was fit the end to suit the hole. We next made a threaded bush C. to fit over the 20 in. portion of the crusher shaft, and fastened this bush to the shaft by means of suitable small screws. The thread on this bush was exactly the same pitch as we wanted at the portion B. Next we made a mit E. to suit the thread on bush C., and fastened to this mit the gear F. To this gear we attached the spider G. in the manner shown. Note that the guide shaft H. fits in a bush in spider G.

Before going further with the description of Fig. 2, let us revert to Fig. 1. Starting with the large gear F mentioned previously, we find that it meshes with a wide face pinion, which in turn drives a 30½ in. diameter gear. From this point, an 8¾ in. pinion meshes with a 30½ in. gear, the pinion being on the countershaft shown in sketch. Referring for a moment to the spider, G, we find that a tool is fastened in the block A, by means of two set screws. Now suppose we are ready to cut the thread at B, remembering, that the old thread was first turned off. We supported the shaft about 3 ft. from the floor, and of course, owing to its extreme weight it never moved. In other words, the cutting tool revolved in this case instead of the work. The main countershaft shown operates at 5 r.p.m. while in the cutting direction, and in backing, speeds up to 12 r.p.m. By the time the power reaches the gear attached to spider G, the speed is considerably reduced, so that there is not too high a

Detail view of tool-holding yoke and guide bush

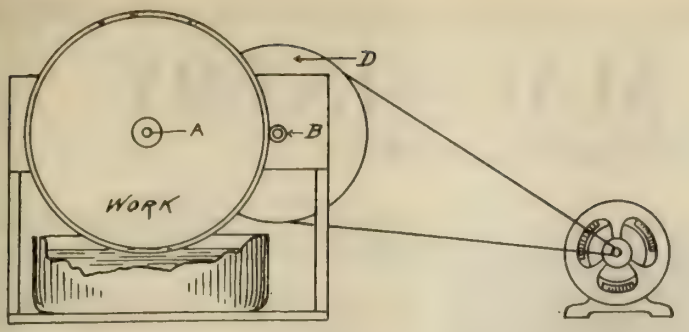


FIG. 1.

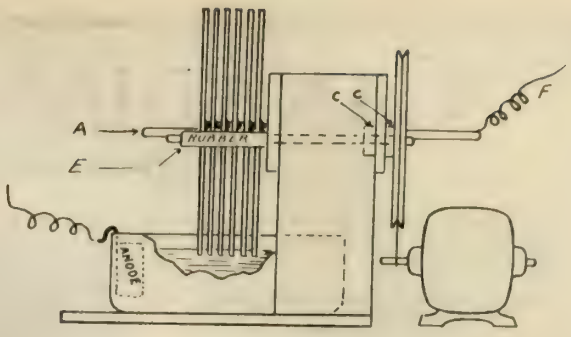

FIG. 2.

Showing method used in gold-plating edges of phonograph discs

speed when cutting such a large piece. Once the power reaches the gear F, it makes the spider G revolve carrying the square thread cutting tool with it. The mit E, moves up the thread on bush C at the proper speed and pitch thus cutting a perfect thread in a very simple manner. This same principle can be carried out on any work which is too big or heavy to swing in the machine.

GOLD PLATING PHONOGRAPH TURNTABLE EDGES

By CHAS. E. HALL

A makeshift arrangement for gold-plating the edges of phonograph turntables is shown in the accompanying sketches. As there happened to be quite a few required, and as gold plating is an expensive operation, only the exposed edge of the turntable, and about ¼ in. of the surface all round was to receive the plating. A wooden frame was made as shown, of suitable dimensions to take the dish containing the plating solution between the uprights. A hole was bored through the two side pieces of the frame, to take a brass rod A on which the work was to rotate, at a height which would just permit the edges of the turntables to dip the required distance in the bath, Figs. 1 and 2.

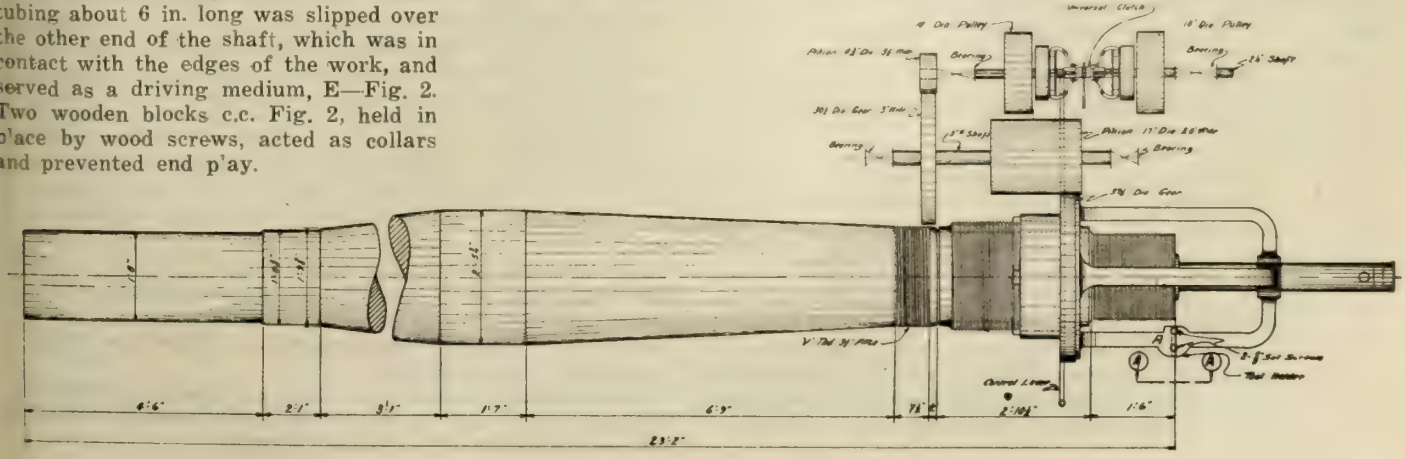
The brass rod was stationary, and a loose fit for the holes in the center of the work. A turntable was placed on the brass rod, and a ½ in. hole bored through the frame in line with the edge. B, Fig. 1.

A piece of ½ in. cold rolled steel was used for a shaft, and a rough turned wooden pulley with a grooved edge, forced on the end. A piece of soft rubber tubing about 6 in. long was slipped over the other end of the shaft, which was in contact with the edges of the work, and served as a driving medium, E—Fig. 2. Two wooden blocks c.c. Fig. 2, held in place by wood screws, acted as collars and prevented end play.

The whole contrivance was driven by a small motor, the cord belt running directly on the motor shaft, as shown, which did the work slowly, but constantly rotated in the plating solution at a given depth. The work could be slipped on and off the end of the brass rod without stopping the motor, which saved a lot of time when scratch-brushing the work, as another batch could be in the solution while this operation was being performed. The work was handled six at a time, the rubber sleeve on the shaft being long enough to drive that number. The current was conducted to the work through the brass rod F-Fig. 2. This arrangement proved to be highly satisfactory, and only took a couple of hours to rig up.

HANDY WHEEL PRESS

The placing of large spur wheels and pulleys on tightly-fitting shafts is a process which generally has to be done by hand and almost invariably involves very arduous labor. An ingenious press has been constructed in Great Britain for the purpose of performing the operation quickly and easily. The wheel is carried on a stand, the upper part of which can be moved under the action of a long vertical lever. When the lever is depressed it operates a pawl and ratchet wheel and thence through spur reduction gear to a rack which carries the wheel forward. The vertical lever is returned to its normal position by means of a balance weight, so that simply by a series of movements of the lever the wheel is forced steadily on to the shaft. This machine is very stoutly built and can be very easily operated.



GUARD THE OIL CAN

It is doubtful if any single piece of shop equipment gets less consideration than the small oil can which is so often seen resting on or near every class of machine tool. Yet the efficiency of the mechanism depends in no small measure on the careful and judicious handling of this small can. The purpose of the oil can is to store small quantities of lubricating oil so that the same can be conveniently applied when occasion requires.

When oiling bearings or sliding surfaces it is important to guard against any foreign substance getting into the oil holes or passages that will destroy or interfere with the free movement of the parts; and yet how often will an observer see an oil can knocked off a machine into a pile of cuttings or dirt, and picked up and used without any attempt to clean the spout before inserting it in an oil cup or oil hole. This form of neglect or carelessness may not be a general one but it is common enough to bring to the attention of those readers who may be desirous of seeing the "insignificant oil can" given the attention it is duly entitled to.

Except when it is being used the oil can should be kept under cover and all surplus oil wiped from the outside to prevent dirt and grit clinging to it. Before placing the spout in an oil hole the end of the spout should be wiped clean. A small particle of grit going into a bearing may do more harm than a gallon of oil will remove.

Don't expect to be promoted unless you are educated for a better position.

Insist on Neatness

A WELL KEPT shop is always a pleasing sight, while on the other hand a poorly arranged plant repels. A factory superintendent who insists on his workmen keeping their benches and machines in orderly fashion, is usually orderly in character and methods himself.

While neatness or cleanliness are not always associated with expert workmanship, it will invariably be found that a man's immediate surroundings reflect the skill and efficiency with which his duties are performed. If a man is directly accountable for the condition of his machine or bench, the general appearance of such is a fair indication of his all-round ability.

Need of Co-ordination

EFFICIENCY is a term frequently used, but often misunderstood. We speak of efficiency in the manufacturing plant, yet in many cases find that while excellent production methods are adopted, there is a lack of co-ordination between the different departmental heads. In large establishments, requiring separate and distinct departments, the efficiency of each department may have attained the maximum, but the plant efficiency may fall short of possibilities owing to the lack of mutual understanding and co-ordination.

In the general run of engineering industries there are what might be termed five distinct sections in productive manufacture, namely, designing, pattern-making, moulding, machining and erection. Each is a tooth in a gear the harmonious and free operation of which requires the absolute absence of friction between any two, or all of the teeth. Where these departments are operated in complete accord with one another, with the various heads conversant with the requirements pertaining to operating details, the basis of production is pretty well established. However, in many plants contrary currents are often responsible for marked inefficiency. Designs are frequently developed and drawings made without due consideration to the economic production of pattern or casting, also the possible contingencies arising from molding, together with the difficulties incidental to machining.

The designer should be familiar with the working methods of the different departments and the facilities provided. He should consider more than appearance and weigh carefully the manufacturing cost.

The chief pattern-maker, molder, shop superintendent, and any other departmental head capable of giving good advice, should be consulted when planning a new machine or any improvement to an existing article, so that all needless expense can be eliminated. Many benefits will be derived from closer department co-operation, and the individual should replace petty personal ideas by the all-round experience of others, for once a department gets the notion that it is the fountain head of information the useful work of co-operation will soon cease to exist. Work together for the greatest possible good, and the finished article will soon give evidence of the beneficial results.

Increase Your Sales by Pictures

THE POPULAR appeal of pictures is a recognized psychological fact. We as publishers know the value of illustrations and sketches, using them wherever possible to explain the articles appearing within the covers of our journal. Do business men, however, make as much use of pictures as they might?

Recently a well known sales manager, noted for his constant search for new sales methods, asked himself why his salesmen could not take advantage of the public's appetite for pictures. He realized they had all sorts of pictures of the stereotyped advertising flavor in their bags, but felt sure this was not the sort of illustrations the public wanted. The result was that he prepared a few sketches showing the action of the product his firm handled, and every salesman reports excellent results from the use of these illustrations. All he did was to show the construction of the product and what it could actually accomplish.

Manufacturers can take a lesson from this, because unfortunately they are inclined to send out photographs showing only the machine standing by itself upon the conventional skids. Follow up your former sales, secure clear photographs of the machines in actual operation, then use these illustrations to close further sales. In addition, make sketches of parts completed, state operating time, type of tools used, etc. Speak the superintendent's language rather than the usual catalogue specification wording, and you will be agreeably surprised at the reception the information regarding your product will receive.

A Nation-Wide Swindle

A NATION-WIDE swindle involving over a million dollars and of which business men are the victims has just been brought to light by the National Vigilance Committee of the Associated Advertising Clubs of the World in New York. As it is possible that the large plunder secured may tempt others to try similar schemes in this country it is well that the trade should be made accquainted with the modus operandi adopted.

The operator, a well dressed businesslike man, calls upon a firm with a dummy directory, (which turns out to be a bogus one), in which appears an advertisement of the firm in question. He asks for payment. If the order is questioned a signed contract is produced, the signature to which has been obtained by one of several fraudulent methods. In most cases, however, the presentation of the printed advertisement is sufficient to lull the suspicion and the amount demanded is paid.

The scheme is not a new one; it was worked for a time in England some years ago, but for much smaller amounts—usually two or three dollars—on the pretense that the firm's name was to appear in larger type in a directory, which of course was a mythical one.

It should be borne in mind that no honest publisher of a directory will require payment without full investigation where any suspicion exists in a customer's mind.

Pig Iron Production in 1921 Lowest in 13 Years

Iron and Steel Market Shows Stiffening Tendency—Scrap Iron and Non-Ferrous Metals Weak—Machine Tools Show Slight Improvement. Small Tools and Supplies Holding Their Own

BELIEVES IMPROVEMENT IS COMING GRADUALLY

THE OFFICIAL figures showing pig iron production in the States for 1921, have just been issued and show the production rate was the lowest in 13 years. Consumption of pig iron, and articles made from pig iron was, however, greater last year than in 1920, as owing to the high prices prevailing in 1920, many concerns carried over their stocks into 1921, believing prices would go still higher. The reverse being the case, production suffered, and while prices of pig iron fell rapidly, it took longer for finished wares to decline. Today, the production rate is 30 per cent. above the average of 1921, although there is a long way to go before the pig iron industry is anything like normal. The market shows a stiffening in tone, but there have been no price changes.

Comparing the production rate of steel in the States from last autumn, the present rate is now 25 per cent. higher. Some question the wisdom of such a rapid gain, while others feel the improvement will still continue. Prices remain the same although there is a stiffening tendency in some quarters. Sheets continue firm, and the pipe market is fairly steady. Pipe mills are running at between 50 to 55 per cent. capacity, while sheet and tin plate mills are around the 57 per cent. mark.

Canadian markets show a slight improvement but this is to be expected with spring approaching. The good weather is helping matters and Montreal reports an increase in demand for iron and steel lines during the week. Boiler tubes, sheets and marine fittings are featured in the above mentioned locality. Toronto finds a good demand for sheets, tubes and shapes. Other lines are moving but slightly. The encouraging feature in this market is the scattered area from which orders are coming. This shows business is picking up in the smaller places, and while the orders are not large, they are more plentiful than a few weeks ago.

Machine tools are quiet, but not so dull as they were a month ago. Each week sees a little added interest, and from present outlook, the improvement in this line, while it is bound to be slow, will continue.

Small tools and supplies are holding their own, and although only a few orders have been closed during the week, prices remain firm.

Scrap metals are still dull and likely to remain so until general business picks up. Copper is quiet also white metals. Steel pipe, oils and greases, and waste is selling at a fair rate, prices on all these lines holding steady. Aluminum is down to 23 cents in Montreal, the former price being 24.50. The railways have not come into the market as yet, but something is expected within a short time.

Toronto

March 15

CONDITIONS locally remain very much the same as last week. Prices have not changed, and while the demand in several lines has improved, the added business is nothing but what was expected as the season advances.

Pig Iron.—Orders in this market are few and far between, and until general manufacturing business picks up, no improvement can be looked for. The quotation figure still remains $27.15, and it is mentioned quite freely that a large producer is considering the closing of his plant for an indefinite period. This of course does not help matters any.

Iron and Steel.—Business in this market is improving as the season advances. Sheets, boiler tubes, and shapes are brisk and other lines are moving at a fair rate. The best feature of all is the fact that orders received are coming in from all over the country, thus showing that things are picking up generally. Prices are inclined to be a little stiffer, although no movement has been made in sympathy with the small increase noted in the steel market in the States last week.

Manufacturers' stocks must be down very low, because the majority of orders received call for immediate delivery, and of course where building material is requested, it is always wanted within a very short time. As the year advances, a further improvement is bound to take place. Following are local quotations:

Iron bars	2 75
Steel bars	2 75
Reinforcing bars	2 75
Steel hoops	3 75
Tire steel	3 00
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in. base	3 25
Small shapes	3 00

Non-Ferrous Metals.—Conditions remain dull in this market. Copper is weak, and red metal while plentiful, is not in much demand. A somewhat depressed feeling exists, and in many cases prices are well down to 1914 levels. Some claim that present quotations do not cover production costs. This seems almost too sweeping a statement, but from authentic sources we find that a very small margin exists when these metals are sold at present prices. Following are local quotations:

Lake copper	17 00
Electric copper	16 75
Castings, copper	16 50
Tin	34 00
Spelter	7 25
Lead	6 75
Antimony	8 00
Aluminum	27 00

Machine Tools.—Every week sees a very slight improvement in this market. Not that business is anything like booming, but buyers are displaying interest in prices. Enquiries are more genuine, and on following these up, dealers report that a fair amount of business has been closed during the week. Usually these orders are secured by aggressive sales methods, and letter writing is only used as a means of interesting the prospect. Later on, the salesman, or in some cases the manager of the machine house calls on the prospective buyer, when prices are discussed in detail. Keen competition exists in all lines.

Small Tools and Supplies.—A spotty market exists at present in these lines, some dealers finding a slight improvement, while others again report a set back over the former week. Actually the market is holding its own and dealers after business, are finding it. Prices remain the same, and discounts are holding firm.

Scrap Metals.—Cast iron scrap is somewhat firmer, and the demand is a little brisker, but the copper scrap market is exceedingly dull. Dealers have large stocks on hand at present which they do want to sell at existing low values, and of course these stocks prevent the absorption of other material coming into the market except at a price lower than its intrinsic value. Red brass scrap is in somewhat better demand, but yellow brass and white metal are both dull. Steel scrap is also very quiet.

Copper, light per 100 lbs.	8 00
Copper, crucible	10 50
Copper, heavy	10 50
Copper wire	10 50
No. 1 composition	8 50
New brass cuttings	11 00
Red brass turnings	6 00
Yellow brass turnings	4 75
Light brass	3 50
Medium brass	4 50
Scrap zinc	3 25
Heavy lead	4 00
Tea lead	3 00
Aluminum	10 00
Boiler plate, per gross ton	9 00
Heavy melting steel	9 00
Axles (wrought iron)	17 00
Rails (scrap)	10 00
Malleable	10 00
No. 1 machine cast iron	18 00
Pipe, wrought	7 00
Car wheel	18 00
Steel axes	16 00
Mach. shop turnings	4 00
Stove plate	16 00
Cast boring	3 00

Miscellaneous.—The waste market is holding its own, quotations being the same, and oils and greases are feeling a slightly better demand although no price changes have occurred. Steel pipe is in fair demand.

Montreal

March 15

THE PAST WEEK has shown a very satisfactory increase in the volume of business moving in iron and steel lines, although no particular line has been the outstanding factor in this general improvement. Merchant bars are still very quiet, and the other quiet commodity in the steel market is structural steel. Apart from these two items the demand for practically all other lines has been gradually improving. There is an unusual volume of building going on at the moment, and a large number of new jobs have been started in the last few weeks. The open weather has been favorable to outside work, but the character of building operations is such that there is no large increase in the demand for steel.

Iron and Steel.—For the past few weeks there has been a good demand for boiler tubes, sheets, and marine fittings. Although this channel seems somewhat limited, it has been responsible for a very fair amount of business. Sheets and plates have been fairly active, the demand being for repair and replacement work. The increasing amount of work being done with reinforced concrete, as the weather moderates, is also responsible for the better demand for reinforcing bars. The railways have not come into the market for rails up to the present, although for some time past it has been expected that orders of some size would be placed. The material is wanted and it appears to be just a matter of time before these orders will be placed. Competition in all lines of steel is very keen, but prices are fairly firm with stocks rather low. As April approaches, the possibility of a coal miners' strike is being discussed. If transportation is tied up, the fact that present stocks in local warehouses are so low, will have a tendency to increase prices, temporarily at least. Inquiries for all lines are coming in much more freely, foreshadowing a further improvement, and a larger proportion of these inquiries are being converted into orders. There does not appear to be the same tendency to shade prices as there was some weeks ago. In fact orders were so eagerly sought in January that the inducements offered a prospective customer, were more than good business would warrant in many cases. Jobbers are doing business on a very small margin, and while some improvement has occurred it is really small, and has not gone far enough to warrant any predictions regarding the future. All signs point to a continued improvement, however.

Rolling mills have been figuring on a certain amount of business in structural steel coming from the railways, but it is not thought that any great volume of business in this line will be taken care of this year. However, enough of it may be offering to fill in some of the gaps that will probably exist between rail orders and other work. Local quotations are as follows:

Iron bars, base, Montreal	2 75
Steel bars, base, Montreal	2 75
Reinforcing bars, base	2 75
Steel hoops	3 75
Tire steel	3 00
Spring steel	6 00

Pig Iron.—There is not any improvement in the pig iron situation. Prices have not changed up to the present although there is a very persistent rumor that a revision will be made shortly. Little information is available outside of the fact that by the time this issue is in the hands of our readers the new quotations may have been given out. The factor that is holding up this department of the iron and steel business, is the situation in the States.

A price war is being waged, and at the moment, price cutting is much in evidence. In many instances the prices asked are far below production costs, and American furnaces are quoting a price delivered, which relieves the customer of all bother and trouble in connection, with payment of duty and clearing shipments. The condition is one that is of a temporary nature and cannot last a temporary nature and cannot last long. In the meantime our producers have been meeting the competition from the States, and in doing so have been forced into the position of having to take a loss in order to do business.

Machine Tools and Supplies.—The last few days have not shown any improvement in the machine tool situation. No changes in price have been reported, and sales have not materially improved. The week has not failed to bring in its quota of new machines offered to the public and of improvements made to standard machines. To one following this feature of the market, it is plain that the engineering departments of the machine tool builders are devoting every effort to improve their product. Probably no line will be better fitted to take care of the good times to come than the machine tool department.

Second in this connection is the machine shop supplies. In the term supplies, is included the line of portable tools, air and electric driven, and many of the new devices that are somewhat difficult to classify owing to their special design and uses. Many specialties are now being standardized and marketed along with standard machine shop supplies. Business in these departments has been good for some time past. Prices have undergone no changes during the week, and business has slightly improved.

Non-Ferrous Metals. — There have been no developments of any importance in the non-ferrous metal market for some time. Copper has been very weak, and it is now quoted at a figure lower than has been seen in the local market for several years. The other metals have not undergone any price changes but existing quotations are not firm. Aluminium has dropped to 23 cents. In spite of the apparent weakness all around, there has been a slightly better demand locally, and present local quotations are as follows:

Lake copper	16 75
Electric copper	16 50
Castings, copper	16 25
Tin	34 50
Spelter	7 25
Lead	6 75
Antimony	8 00
Aluminum	27 00

Scrap Metals.—Business in the scrap metal field remains very dull. Prices have not changed and only a very small volume of business is offering. Rumors of shortage of scrap metal have had no effect on the demand, which continues to be very poor. There is very little likelihood of any shortage developing, as the increase in demand will be so gradual that supplies will have an opportunity to accumulate. The demand is so slight that little effort is being made to collect the supply available. Local quotations are:

Copper, light	8 00
Copper, crucible	10 50
Copper, heavy	10 50
Copper wire	10 50
No. 1 machine composition	8 50
New brass cuttings	6 00
Red brass turnings	6 00
Yellow brass turnings	4 75

Reinforcing bars, base	2 75
Steel hoops	3 75
Tire steel	3 00
Spring steel	6 00

Pittsburg

March 15

PITTSBURG,—(Special to Canadian Machinery).—The official report of pig iron production in the United States in 1920 has just been issued, making the following comparison, in gross tons: 1913, 30,966,152; 1914, 23,332,244; 1915, 29,916,213; 1916, 39,434,797; 1917, 38,-621,216; 1918, 39,054,644; 1919, 31,015,-364; 1920, 36,925,987; 1921, 16,688,126.

The particular record made by the 1921 production was that it was the smallest in 13 years, this being by far the greatest backward step, in point of time, ever made. The 1908 production was the smallest in seven years, the 1894 the smallest in six and the 1876 production the smallest in five.

Consumption of pig iron and things made from pig iron was much greater in 1921, as compared with 1920, than indicated by the pig iron production figures. On account of the high prices in 1920, giving the impression that everything was very scarce and might remain scarce, men carried stocks over into 1921 which otherwise they would have made more effort to liquidate in 1920. The high prices tended to discourage consumption in 1921. While pig iron prices fell rapidly, it took more time for the finished wares such as the ultimate consumer buys, to decline.

The conclusion is unavoidable that pig iron production in 1921 was much below a normal relation to the general business conditions existing, even though those conditions were not good, and it seems to follow that it is entirely unlikely that there will be another year with as light production. Even at the present time pig iron is being produced at a rate 30 per cent. above the average rate in 1921.

Steel production.—From the monthly report of the American Iron and Steel Institute of the steel ingot production of 30 companies, it may be estimated that the steel industry as a whole produced steel ingots in February at the rate of about 26,850,000 gross tons a year, against a rate in January of 22,750,000 tons. There was continuous increase in the rate during the two months, from a rate well under 18,000,000 tons at the end of December to a rate of about 29,000,000 tons at the end of February. The 29,000,000 ton rate has remained practically unchanged to this date.

The only question about the steel market is whether the gain has not been too rapid, about 70 per cent. in two months, following the dip in production towards the close of the old year, a reflection of the season of year as well as the annual inventory taking. Compared with the production last autumn the present 29,000,000 ton rate is 25 per cent higher rather a sharp gain when spring has not yet really arrived. Here and there one encounters a prediction, made by men who do not seem to realize what has already occurred, that conditions in the steel industry are now about to improve, but the real point is whether all the gain already experienced can be held. While reports in the different branches of the steel market in the past couple weeks have as a whole been somewhat favorable, there is really some question whether the total of steel buying thus far in March has been at as heavy a rate as obtained in February. It is possible that purchases recently were being swelled by buyers anticipating trouble in getting deliveries after April 1, on account of the prospective suspension at the union bituminous coal mines. Some steel buyers seem to have been alarmed by the prospect, while steel producers are not. The latter have stocks of coal averaging fully one month's requirements and think this will be sufficient, in conjunction with such deliveries as they will still get, even at the worst, from the non-union fields, like the Connellsville region.

Steel Prices. — Bars, shapes and plates, which had reached relatively lower levels than other finished steel products, now face the possibility of a slight stiffening. The Jones & Laughlin Steel Company, which had been a particularly aggressive seller, has announced an advance in its price to 1.50c, and its competitors estimate that in its sales campaign it accumulated enough business to carry it for 60 days at its present rate of operation. The market remains quotable at 1.35c to 1.40c as formerly, and the advance by this large independent is therefore in essence a withdrawal from the market, but the removal of this particularly strenuous competition seems already to be exercising a somewhat stiffening effect on the market, and 1.40c is now a more common quotation than 1.35c. Other sellers, while very competitive, are indisposed to tie up much tonnage for forward delivery at extreme low prices, preferring, if possible, to work their prices up first.

Sheets continue firm at 3.00c for black and 4.00c for galvanized, where they have been for more than three months. Pipe is being shaded by a considerable margin in some districts, but the shading is not general, and on the whole the pipe market may be regarded as fairly steady.

Mill Operations.—As noted above, the general rate of steel mill operation, as shown by ingot production, has undergone no material change in the past couple of weeks or more. In individual mills there may be slight changes. The pipe mills are running a trifle slacker, at between 50 and 55 per cent. of capacity, while sheet and tin plate mills seem to have gained a little. The Steel Corporation's unfilled obligations at the end of February are reported at 4,141,069 tons, indicating a decrease during February of 100,069 tons, a favorable showing when properly considered as it suggests that some contract tonnage long on books came to life by being converted into actual shipping orders, for the corporation's shipments were about 57 per cent. of capacity in February against 47 per cent. in January. The unfilled obligations decreased by 26,736 tons in January. Comparing shipments and unfilled tonnage it appears that in January the new bookings amounted to about 45 per cent. of capacity while in February they amounted to about 49 per cent.

The various pig iron markets show, a more stiffening than declining tendency, as prices are quoted higher at both Philadelphia and Chicago, while Alabama iron is firmer if not actually higher. In the local market there have been no price changes, Bessemer being $19 to $19.50, basic $17.75 to $18 and foundry $18.75 to $19, f.o.b. valley furnaces, freight to Pittsburg being $1.96.

Connellsville coke for spot or prompt shipment remains quotable at $3.25 to $3.50 for furnace and $4.25 to $4.75 for foundry, thus holding the recent 50 cent advance.

Preliminary work on the plant of the Three Rivers Pulp and Paper Company, Three Rivers, Que., which is capitalized at $3,000,000 will be started in March, 1922.

The decrease of $699,882 in the net debt of Canada during the month of February, as compared with an increase of $4,290,143 in the same month last year, is shown from the financial statement issued from the Finance Department, Ottawa.

BELIEVES IMPROVEMENT TO BE COMING GRADUAL

Speaking of the recent improvement in business, Judge E. H. Gary, chairman of the United States Steel Corporation, says that although there has been a gradual improvement in business, he has not seen substantial evidence of a general and rapid recovery to normalcy. He believes, however, that business laws will sooner or later compel stability, progress and prosperity. He says that probably it is better so, for the natural laws applying to business are grinding slowly but surely and will compel, sooner or later, stability, progress and prosperity.

"If the laws of the country shall be sufficiently enforced to permit every individual to utilize his talent and energy without forcible interruption," says Judge Gary, "we shall soon see the prosperous conditions for which we have been anxiously and expectantly looking for many months. The sun of prosperity is still shining, though it has been unnecessarily obscured."

The Flexible Shaft Co., Canadian branch of the Chicago Flexible Shaft Co., are now manufacturing their line of Stewart industrial furnaces at their factory 349 Carlaw Ave., Toronto. The Canadian plant has been in operation for some months, but it was only recently that the manufacture of furnaces was commenced. L. E. Fitzpatrick is general manager.

With business in general still somewhat undergoing the process of reconstruction and with many reports of unfavorable conditions in various industries it is very reassuring to hear of an industry going at top speed, working overtime and then unable to fill the demand for their products in the Canadian and other export markets. This is the condition in which the General Motors of Canada find themselves. The plants at Oshawa and Walkerville are running full time and quite a number of the departments are working overtime. The daily output for the past three months has been 150 finished automobiles. The schedule for the next two months calls for a daily output of 175 to 200 finished automobiles. This will be a larger schedule than Canada's premier automobile manufacturers—the General Motors of Canada—have ever turned out in their history. The payroll of General Motors of Canada, Limited, for the month ending February 15th, was at the rate of $446,000 a month, showing the great strides this institution has made. It is estimated that at least 8 million feet of lumber will be used in this production. Huge quantities of leather trimming fabric, curled hair, brass, aluminum and malleable iron castings, springs, tires, sheet metal works, paint, varnishes, enamels and a hundred and one other commodities will be required. The list is so great that dozens of manufacturers will participate in this activity.

SELECTED MARKET QUOTATIONS

Being a record of prices current on raw and finished material entering into the manufacture of mechanical and general engineering products.

PIG IRON

News From the Industrial Field

The province of Ontario is now producing 6 per cent. of the world's gold.

Annual General Meeting of the Canadian Manufacturers' Association will be held in the Algonquin Hotel, St. Andrew's by the Sea, N.B., on June 20, 21 and 22.

The Oakville town council has decidded on the installation of an auxiliary pump for emergency water works purposes. This will either be gasoline or steam driven.

The Brown, Boggs Co., Hamilton, Ont., have opened an office in the Holbrook Bldg., 77 Florence St., Toronto, and have appointed A. B. Walker as their Toronto representative.

The Toronto Transportation Commission is trying out a new double-decker bus, manufactured by the Eastern Canada Motor Truck Co., of Hull. The executive of this company is composed entirely of returned soldiers.

The work of rebuilding the Frankford canning factory at Frankford, Ont., which was destroyed by fire last year, has commenced and will be pushed forward with all possible speed so as to be ready for the season's work.

A contract said to value approximately $60,000,000 has recently been closed by the Saguenay Pulp and Power Co. The business includes an order for about one million tons of ground-wood pulp and 450,000 tons of sulphite pulp. The purchasers are a group of English newspapers including those owned by Lord Northcliffe and Lord Burnham.

The Standard Steel Construction Co., of Welland, Ont., has recently been appointed sole Canadian representative for the sale and distribution of the products of the Irwin Iron Works of New York City, consisting of steel floor gratings and safesteps. These floor gratings are used almost exclusively in the extensive subway work in the metropolitan district of New York.

The Canadian Government has appointed G. A. R. Emery, one of the officials of the Department of Commerce, to study the possibilities of reviving trade between Canada and Newfoundland. For the past few years this trade has fallen off about 50 per cent. It is hoped that Mr. Emery's trip will result in establishing renewed trade activities between the two countries.

Stabilization of the electric industry is reflected by the monthly business reports of the Packard Electric Co., of St. Catharines for February, which showed a 10 per cent. increase over any other February in the company's history. The shipments for the month were 90 per cent. of that of the banner year of 1920.

Gordon M. McGregor, vice-president and general manager of the Ford Motor Co., of Canada, passed away at the Royal Victoria Hospital in Montreal, last week, following an operation.

Statistics on the population of the state of New York issued by the Census Bureau, show that there are 99,792 natives of Canada in the State. There are 280,500 natives of Ireland; 120,299 from England and 34,155 from Scotland.

Figures of the operation of the pulp and paper industry in Canada during 1920, just issued by the Dominion Bureau of Statistics, set forth in a striking manner the rapid growth of this branch of industrial effort during recent years. There are 100 pulp and paper mills all told; capital investment is given as $347,553,000.

The Page-Hersey Co., Welland Ont., has announced that it is adding 250 men to its staff this week at the Welland plant and is resuming the old schedule of day and night operation. The pipe mills have been inactive in recent months but now business is being secured enabling the company to increase its working force.

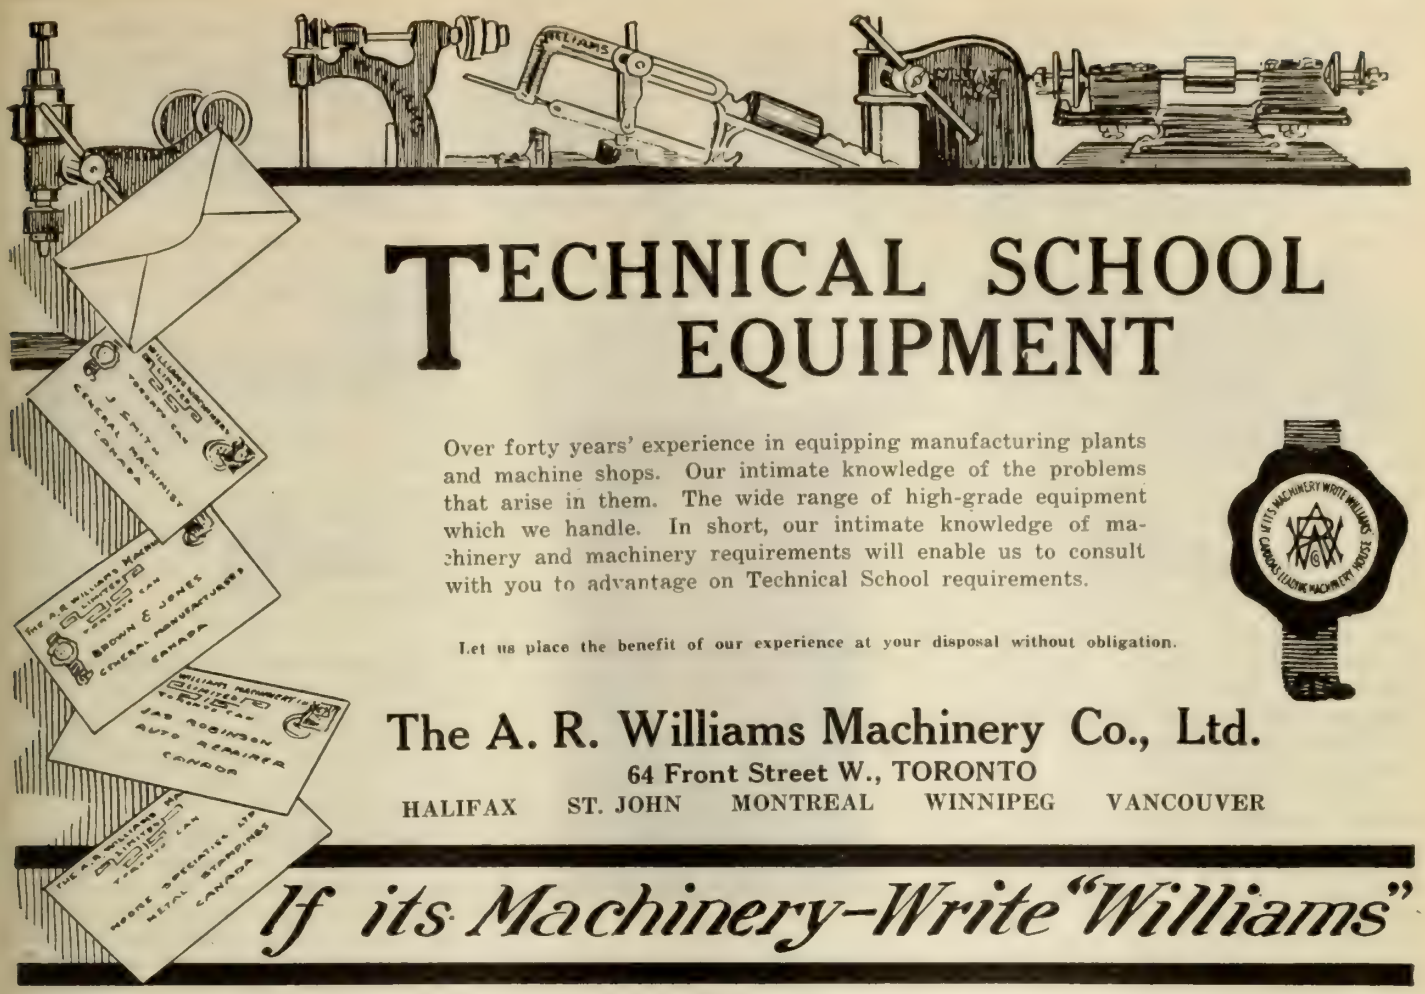
Inquiries for steel on the part of manufacturers have been heavier in the last fortnight than for the earlier part of this year. This evidence, together with the actual business booked, indicates that there is a more lively interest in replacing stocks and preparing for the larger trade that is expected in the spring months.

Industrial circles generally are gratified at the increasing value of the Canadian dollar, which has almost reached par, and there is a general feeling in the Canadian coal trade that when the adverse exchange against Canadian money disappears, as it will soon, the American railways cannot with good grace continue to ask that freight be prepaid in United States funds.

F. C. Hart of the Department of Agriculture was in Cobourg, Ont., this last week and organized the Co-operative Dairy Co. Directors have been appointed and a charter has been applied for. It is stated that, it is the purpose of the new company to purchase the Cobourg Creamery Company's plant and carry it on as a co-operative concern.

Fire which threatened the entire plant of the Standard Steel Limited at Port Robinson was extinguished by the good work of the Welland Fire Department. It is believed that the fire started from an electric stove in a shanty at the foot of the tank. The tank was saved by water from a forty foot well which was practically dry when the fire was under control.

Peterborough's new $300,000 filtration plant is now in partial operation, and the improvement in the quality of water is distinctly noticeable. The plant is being tested out each night and the day requirements are taken from the two million gallon reservoir. This plan will continue until the tuning-up process has been completed to the satisfaction of the contractors and engineers.



After a period of idleness for many months due to business depression the mechanics of the metal trades industry are beginning to return to work. This is according to a statement made by the Secretary of the Toronto local union. He also stated that a number of men are resuming their places in machine shops and this indicated to him a fairly prosperous season.

The general manager for Price Bros. Limited, of Quebec has stated that the first shipment of an order for 13,500 tons of newsprint which his company have contracted for supply to the London Daily Express, England, will be made this month. The first shipment will consist of 1000 tons and will be made through the Cunard-Donaldson line. The total value of the shipment is approximately $900,000.

Power to borrow several million dollars to build a new city hall in Montreal, Quebec, may be granted by the legislature when the Montreal bill comes for final consideration before the legislative council. The old city hall which has been in use for the past thirty years was burned down early this month and the building was completely demolished. No time will be wasted in getting the new plans under way for the erection of a new city hall.

The Oak Tire and Rubber Co., Oakville, Ont., is one of the companies who were not a party to any large contracts at the time the depression in prices of raw materials took place. It is indicative of an upward swing to better business conditions when manufacturers are working to the limit. This company's factory is working to full capacity, 22 hours per day, and the unfilled orders on the books amounts to over one hundred thousand dollars.

Thomas Southworth, managing director of the Deloro Smelting and Refining Co., has recently moved to Ottawa, to look after the interests of the company, the branch office having just been removed to that city. For the past twenty-five years Mr. Southworth has resided in Toronto, during which time he has occupied different important positions in Government service. He has been associated with the Deloro Smelting & Refining Co., for the past twelve years.

D. A. Campbell, B. A., director of technical education for Alberta, has resigned his position to accept the appointment of principal of Sarnia Collegiate Institute and technical school at a salary of $5,000 a year. Mr. Campbell will take up his new duties after Easter. For many years Mr. Campbell was head of the science department of Ottawa collegiate institute.

In the course of his address before the Canadian Institute of Mining and Metallurgy, C. D. Corless, president of the Institute, referred to the tremendous coal reserve in Canada, estimated at one thousand two hundred and thirty four billions of tons, or thirty-five thousand times the present annual consumption. He pointed out that although Canada was spoken of as an agricultural country only 15 per cent. of the area of the Dominion was suitable for cultivation, while 90 per cent. would undoubtedly produce great mineral wealth.

Another indication of the growth of the automotive industry in the Dominion of Canada is that prior to 1911 there were less than 10,000 motor vehicles of all types in the country, and at the end of 1921 over 460,000 cars, trucks and motorcycles were registered. The increase from year to year was gradual up to the end of 1916. During the following year registrations jumped from 120,000 to over 198,000. In 1918 the registrations jumped from 270,000 to 330,000. In 1920 the yearly increase was over 70,000 and last year it was more than 66,000.

As the result of prospect of a big building boom which is expected to take place in Toronto and other cities and towns in Ontario within a few weeks, all the brick making plants near Milton, Ont., are engaging more men and have started on a 10-hour day. The woollen mills and foundry company are both working day and night and other industries in the town are showing signs of improved activity.

Large dealers in the Canadian textile trade seen at Ottawa quite recently report that the woollen mills in the Ottawa valley and elsewhere in Canada are booming. They report that practically all the woollen mills of Canada are working at 100 per cent. capacity with at least three months orders ahead. Rapid improvement has been made in the preparation of dye stuffs and the method of manufacture are said to be so superior that they are rapidly sending out imported goods on a business of quality rather than tariff protection.

The Aluminum Steel Products Co, one of Owen Sound's latest industries, reports a fair demand for small aluminum castings. They have installed two casting machines, on which high production is possible, and their dies are made in their own machine shop. A large order was recently received from the Ford Motor Co., on a small engine accessory.

Thos. Barber of Barber & Son. Meaford, manufacturers of hydraulic machinery, has returned from Holyoke, Mass., where he had tested, in the experimental flumes there, two water turbines of a new type. This Meaford industry reports that while actual activities in the hydraulic field have eased off considerably an exceptional number of enquiries calling for estimates, have been coming through. This, at least, is encouraging.

The D. McKenzie Machinery Co., Guelph, manufacturers of metal and woodworking machinery recently shipped a carload to eastern points. They report a very encouraging development in the machinery market and consider it indicative of a much better buying feeling generally.

The Preston Woodworking Machinery Co., Preston, recently shipped two woodworking lathes to the technical school at Prince Rupert, B. C. They have also equipped the vocational department at Chilliwack, B. C., and have installed three motor-driven lathes in the new London collegiate.

The Sandwich Foundry Co., Limited, Sandwich, Ont., are exceptionally busy on contracts for the Ford Motor Co., and Canadian Products, Walkerville. Their foundry was formerly known as International Castings, Limited. This concern passed out and the plant was taken over by seven practical foundrymen who have been quite successful.

The R. H. Cunningham Co., Walkerville, electrical engineers, are moving to London, where they will occupy a building at the corner of Glebe street. Before leaving Walkerville, they will install at the plant of the Postum Cereal Co., Windsor, an electric oven for cook-

ing cereal, a process in which gas has been used heretofore.

The Canadian Detroit Twist Drill Co., Walkerville, Ont., report an improvement in the demand for drills and small tools, especially from the motor car industry. This company recently increased their equipment and extended their plant for the manufacture of motor valves.

The dry dock, ship building and repair plants owned and controlled by the Grand Trunk Pacific Railway, have been taken over by the Canadian Government. The apparent intention is to operate them in connection with the Grand Trunk Pacific Railway and the Grand Trunk Pacific Steamship Company, both of which are now under control of the Canadian National Railway. Prince Rupert, B. C. is to be made a terminal point. The ship repair plant is as complete as any on the Pacific Coast and includes a machine shop, two covered shipbuilding sheds, a foundry, blacksmith shop and power house. The ship-building plant is equipped with two ways, of sufficient size to permit construction of large vessels.

Bridge construction is being undertaken by the T. & N. O. Railway Commission and by the Hydro-Electric Commission of Ontario. This will involve the use of more than 3,000 tons of steel. A hydro transformer station is to be erected at the western portion of Toronto that will require about 500 tons of structural steel. The structural steel trade looks much better than it did a fortnight ago. Certain firms that had little business ahead no more than two weeks ago have since been in the market for fair sized tonnages of steel. Inquiries for steel on the part of manufacturers have been heavier in the last two weeks than for the earlier part of this year. Evidence together with actual business booked, indicates that there is a more lively interest in replacing stocks preparing for the larger trade that is expected in the spring months.

With the powers recently granted to the Montreal Service Corporation and the Canadian Light and Power Co., the development of the Ottawa River at Carillon will be proceeded with as soon as weather conditions will permit, a considerable portion of preliminary work having been already accomplished. It is further claimed that the consolidation will finally result in the production of upwards of 300,000 h.p., much of which has already been contracted for. To carry the work to completion, a total of $40,000,000 will be required, it is claimed, all of which will be expended during the next two years.

Speaking recently on the possible trend of business this year, Robert Hobson, president of the Steel Co. of Canada, expressed the opinion that conditions should be nearly normal by autumn of this year, according to present indications. He stated that although Canadian firms are not overwhelmed with orders, he had received reports which justified his belief that there is a great cause for optimism in the immediate future. People may look for a marked increase in Canada's trade, both export and domestic, within the next few months, according to Mr. Hobson's view. This is believed to be particularly the case in the steel industry. The evidence of recovery of activity in the steel business is not merely local or Provincial. Reports from the leading production and distribution centres of the continent show a widespread increase of activity.

H. GRAHAM

H. Graham has been appointed general manager of the Bond Engineering Works, Limited, of Toronto. For the past six years Mr. Graham has been purchasing agent of the Canadian Vickers Ltd., of Montreal.

Owing to space not being available we are holding over articles on several schools in Ontario. These will appear in later issues.

J. Blair, of the Alfred Herbert Co., Toronto, is making a business tour of Western Ontario.

The Standard Stone Co., Windsor, Ont., intends to erect a modern factory building and to install machinery for the milling of stone.

The governors of the General Hospital Brantford, Ont., are considering the installation of an auxiliary power plant to provide against the possibility of inconvenience such as they experienced during a severe ice storm when power and light was off for many hours.

A considerable amount of construction work is in prospect in Kitchener and Waterloo for the coming building season. A new city hall is planned for Kitchener and a collegiate institute and technical school for Kitchener and Waterloo jointly. In cluded in the Industrial buildings projected are the following: an addition to the Greb Shoe Company premises, erection of a new factory for the Dominion Skirt Co., Ltd. 2 automobile sales rooms and garages are proposed in the business section of Kitchener.

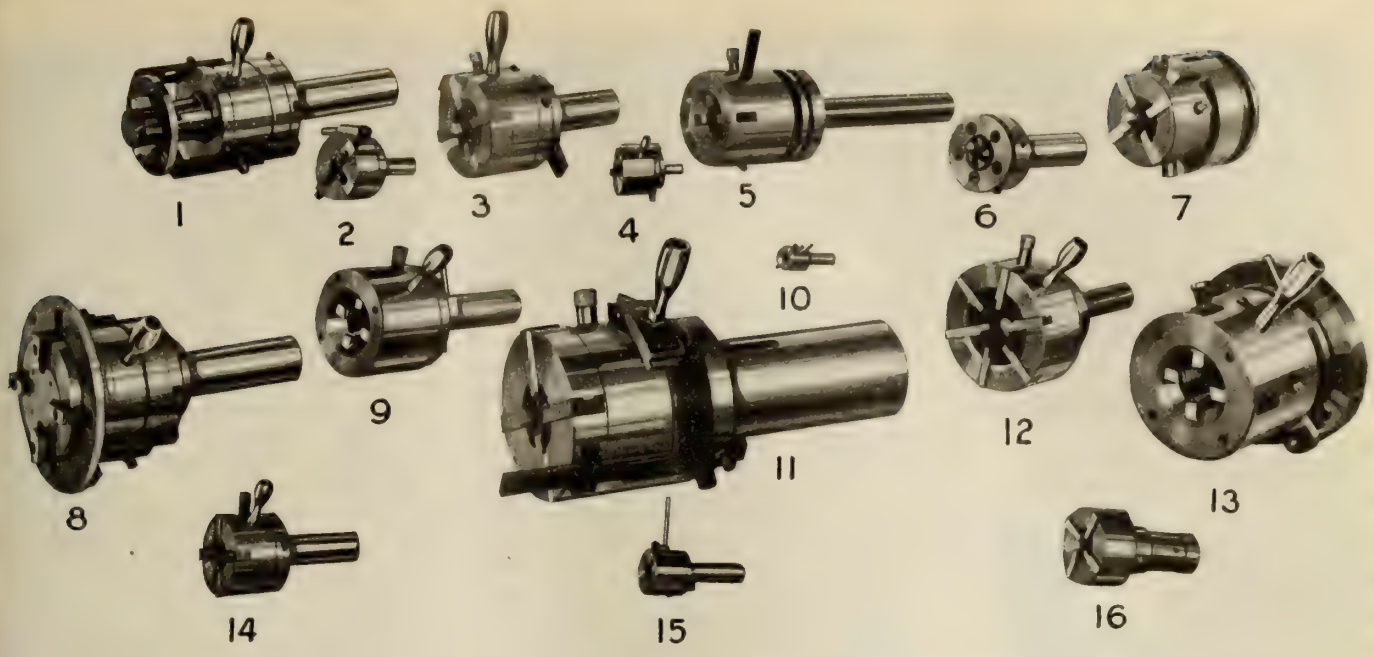
BOWMANVILLE BUSY

The town of Bowmanville, Ont., has recently completed concrete sewer and pavement work costing $78,000.

Ross Can Co., of Bowmanville, have enlarged their premises and report an improvement of business over last year of about 65 per cent.

The brick works of Bowmanville are adding a pottery to their plant. Machinery is already delivered and installation is under way.

The Thompson Knitting Co., has recently purchased a building from the town of Bowmanville, at a price of $20,000. The firm has just contracted for an order of $60,000 worth of hosiery and is employing 115 hands.



The Bowmanville Foundry, under the management of R. H. Rehder & Co., has just completed extensions to the plant costing about $40,000. Eighty men are employed.

The Notre Dame Investment Co., Montreal, Que., is now forming a separate corporation for the erection of a 130 suite apartment block on the north side of Broadway, Winnipeg, Man. Work will start in the spring. Approximate cost $1,000,000.

The Detroit and Windsor Ferry Co., Windsor, Ont., is asking permission from the city to build their new docks forty feet farther into the river than the present docks. More than $300,000 will be spent this summer, according to the present condition of the company, if satisfactory arrangements can be made with the city.

A report issued by the Newsprint Service Bureau of New York, available, carries an interesting supplementary message to the Canadian Government figures. Of the Canadian mills that belong to the "Service," production during January was 81,418 tons as compared with 71,518 tons January one year ago. This represents 92 per cent of maximum for the month of January this year. In the United States the mills produced 93,389 as against 101,292 one year ago, a decline of nearly 8,000 tons.

Tenders for construction of the new east end technical school in Toronto will not be called for until after the signing of the agreement between the provincial government and the city, by which the government will undertake a portion of the expense, it was decided by the advisory industrial committee of the board of education last week. Efforts are being made to divert certain non-technical and academic subjects from the Central Technical School to the different branches, so that more time may be devoted to practical instruction. Principal McKay predicted an increase of 500 to 600 in the number of pupils by next fall. It was decided to advertise for a "vocational advisor" whose duties would consist in advising school children as to their life work. The high qualifications required in such an officer were emphasized by members of the committee.

—AND OTHERS

These are only a few of the Various Arrangements Of Geometric Thread Cutting Tools

Geometric Automatic Opening Die Heads and Collapsing Taps are adapted for use on the Turrets of practically all makes of Hand and Automatic Screw Machines and Turret Lathes. Where requirements are unusual, they are arranged to meet the most exacting conditions of machine and work.

HAS MADE A SUCCESS BY GOOD MANAGEMENT

Guilio Gatti-Casazza, who began life as an engineer in the Italian Navy, is now the world's greatest operatic director. He has just renewed his contract with the Metropolitan Opera Company in New York, which will give him, at the end of three years, eighteen years' service. He has reduced the whole opera and its management to a business basis, no doubt as a result of his training as an engineer. Formerly people attended operatic performances because of the appearance of this or that individual singer. To-day they go on account of the Opera as a whole. This condition could be brought about only by raising every detail of each production to a uniform high plane of merit. The orchestra and chorus have been trained to an equally high degree of skill. The scenery surpasses in beauty and appropriateness the settings used in any other opera house in the world. Canadians have an interest in Mr. Gatti-Casazza because his wife, the prima donna—Madame Alda—is British, being a native of New Zealand and very popular before Canadian audiences.

The Northern Ontario Light and Power Co., Cobalt, Ont., is considering the development of the Sturgeon Falls project. There will be approximately 7,000 Horse power. The cost will be between $350,000 and $600,000.

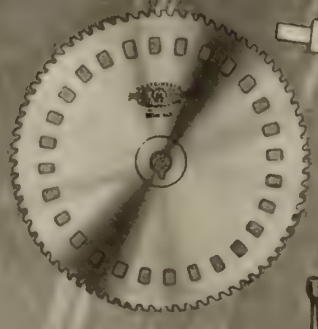
CONDITIONS SHOW DECIDED IMPROVEMENT

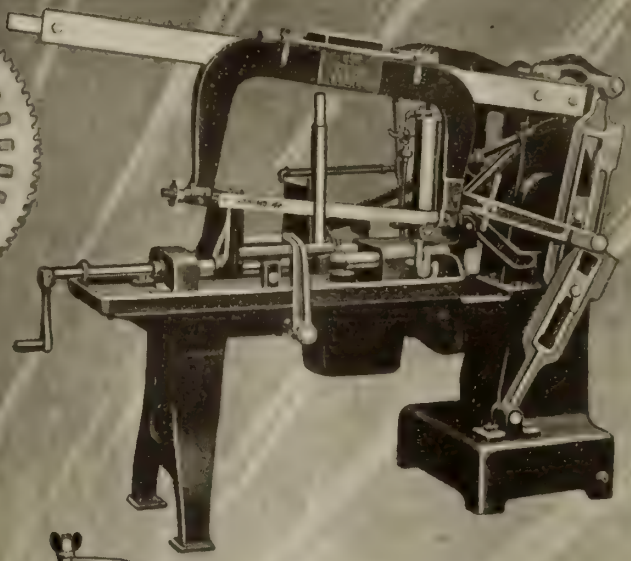
PEAKING of business conditions in the States, Mr. Eisenman, national secretary of the American Society for Steel Treating, told Canadian Machinery that he has recently traveled from New York as far west as Chicago, visiting the important industrial centers en route. In these places he has found a very optimistic attitude and trend, which is not a result of a condition of the mind, but an actual added interest in business.

He claims that people are realizing that prices have dropped to the lowest minimum in some cases, and that they are again beginning to buy. "They do not expect revival overnight," remarked Mr. Eisenman, "but they do look for a gradual increase in business."

The production of the steel mills in the States has increased 10 per cent. during the past month, according to his statement, and now shows a 50 per cent rate. "To reach normal they only require 80 per cent. production," remarked our informant, "because such a rate was normal before the war. In other words," concluded Mr. Eisenman, "the steel game was over-expanded during the war, but if we get back to 80 per cent. of war time activities, we will have reached 100 per cent. of normal times. There is no need to worry about the other side of the line. We have passed the worst, and are now on a steady upgrade."



In connection with the proposed operation of one-man cars on the Pt. Arthur Civic Railway, we understand that the city Public Utilities Commission is awaiting the hearing of its application to the board of Railway Commissioners to operate such cars in that city. Pending a decision in this matter, which will have considerable bearing on whether or not one-man car operation will be extended to the entire system, instructions have been issued to fully equip one of the existing cars with safety devices, which will include pneumatic door and safety devices in order to demonstrate the safey and reliability of the car and the one-man operation. An order has been given the Canadian Westinghouse Co., Hamilton, Ont., for the safety devices and the car will be equipped as soon as they are delivered. It is hoped that by the time this is done the Board of Railway Commissioners will have made such a decision as will enable the extension of one-man car operation to the entire car system.



The Western University London, Ont. is having plans prepared for a two-storey University building including steam heating system. The approximate cost will be about $1,000,000.

The America Swiss File and Tool Co., of New York, are issuing a descriptive folder in connection with their various types of files.

NEW AIR-TIGHT BLAST GATE
Light, Strong, Compact, Inexpensive, Quick-Acting. Threaded or Flanged connections.

Carlisle, Penna.
We are using your Blast Gate as an outlet valve on a starch tank. This tank contains a very heavy grade of starch—just liquid enough to flow. This heavy substance clogs the ordinary valve but your blast gate has, to date, given perfect satisfaction.
C. H. Masland & Sons, Inc.

ELIMINATE VALVE INEFFICIENCY

Hundreds of former valve users have found the remedy by installing Rockwell New Air-Tight Blast Gates.

This wonderful control device has proved an ideal substitute for expensive, heavy, cumbersome and slow-acting gate and globe valves when used for:

Air and Gases of Various Kinds

Blast furnace coal and lime dust
Counteracting back pressures
Distillation processes
Pulverized coal
Chemicals handled through pipes
Gas engine exhaust lines
Soot chutes
Starch

Present industrial conditions make it urgent that you investigate the economy and efficiency of this New Air-Tight Blast Gate. Ask our nearest branch for Circular 210-T.

LET US HELP YOU.

The above pictured helps are the result of a constant effort to help drill users drill more holes per drill. The suggestion regarding drill use and abuse set forth in these helps has been gained from almost 48 years of actual drill manufacturing experience.

The "Little Doctor" card tells the drill press operator the symptoms of drill abuse, its cause and remedy.

The "Ready Reference" Charts give information on decimal equivalents, speeds and feeds, lubricants and tap drill sizes especially for the New National Thread system.

The "Yellow Slide" gives you a table of cutting speeds for drills 1/16″ to 3″ and a fund of useful information on drill abuses, its cause and remedy.

The "Red Slide" quickly gives you speeds and feeds of drills, taper drill sizes and decimal equivalents.

"Factory Facts" is a condensed catalog of the more widely used "Cleveland" Tools and contains some factory facts for the up-to-date shop.

We will be glad to furnish this material in reasonable quantities to those who request it and of course free of charge.

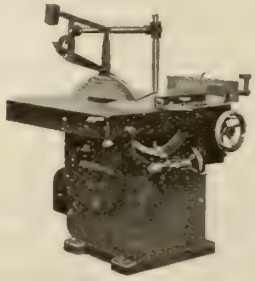
What Are Your Needs?
We can supply them.

THE following list of machinery forms only a very small portion of the machinery we handle. We are prepared to supply any machine you are in need of, at a price that will suit you. Keep us in mind when ordering equipment.



DOUBLE ARBOR Universal Saw Table, especially designed for Technical Schools.

Pattern Lathes
Engine Lathes
Bench Lathes
Turret Lathes
Planers

Shapers
Grinders
Drills
Saw Tables
Hack Saws, etc.

Everything in metal-working and wood-working machinery.

THE

TRADE K—T IE MARK

FOUNDRY

GALT, ONT.

Do Your Castings Cost Too Much?

A rearrangement of your patterns might cut their cost 25 per cent.; a different method of molding them might double your production at no increase in molding cost. We can advise you and we have expert metal and wood patternmakers who are able to make any changes that may commend themselves to you.

If you need some new Patterns

send us a sample, blueprint or sketch, and ask for our advice. It won't cost you anything. If our advice is good and commends itself to you, it is only fair to assume that our work will be equally satisfactory, and we need the work as badly as you need the patterns.

We are in a position to do turning, boring, drilling or other semi-finishing operations on castings supplied by us. Ask us.

We have for our and your requirements, a large stock of assorted White Iron Stars, suitable for light agricultural to medium weight machinery castings, while they last, at 8 cents per lb. F. O. B. Galt.

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

ANNOUNCEMENT

THE International Business Machines Company Limited, takes pleasure in introducing to the Canadian public an important new invention, the Electrical Recording Door Lock.

The recording Door Lock is a superb piece of mechanical equipment for which we are in a position to say positively, there will be an instant and widespread demand.

When you employ this equipment the door of your office, or your store, or your factory, cannot be unlocked without electrically registering:

(1) Whether the door was opened from the outside or from the inside; (2) on what day; and (3) by which employee.

The International Recording Door Lock

is simply controlled by each employee's specially designed key, though in appearance it resembles an ordinary lock.

The manifold advantages of this equipment will be immediately obvious. It protects your goods; it protects your store; it protects your office and all the valuables that may be contained in them. It places the responsibility directly upon the person who entered, showing in print the exact time he entered, how long he remained and the exact time he left.

This wonderful lock is wired to an autographic register in which is a roll of paper. On this roll the printed record is made automatically when the key in the door is operated. Eight keys may be had for any one door. Eight doors may be related to the same autographic recorder.

At the same time the autographic recorder, a perfect time piece, may be used for the other employees who do not have keys as a time recorder or place to register their attendance.

To see this equipment is to marvel at its simplicity, and the wonderful precision with which it functions.

The International Business Machines Co., Limited, has expended a fortune in preparation for large scale production of this equipment. We know the demand will be tremendous. The price is $275 for the recording autographic instrument, and for each lock requested, $55.

Never has an invention comparing with this been sold at so reasonable a price.

Fire Chiefs and Police Chiefs have pronounced that it fills a long felt want in giving a necessary record for any store, office, or store room, where valuables or merchandise are kept.

You can have this equipment demonstrated to you in a few minutes at any of our Sales Offices.

INTERNATIONAL BUSINESS MACHINES CO., Limited

FRANK E. MUTTON—Vice-President and General Manager. HEAD OFFICE and FACTORY—300 Campbell Avenue, Toronto.
For your convenience we have Service and Sales Offices in Vancouver, Winnipeg, Walkerville, London, Hamilton, Toronto, Ottawa, Montreal, Quebec, St. John, N. B., Halifax, St. Johns, Nfld.

Also manufacturers of Dayton Computing Scales and International Electric Tabulators and Sorters.

STAYBOLT TAPS

The Better the Man, the More He Appreciates Them—

Not only good when new, but heat treated and seasoned to maintain this goodness. Can be ground on face of cutting edge without affecting their size. That's why you'll find Pratt and Whitney Stay Bolt Taps on the job long after cheaper, "just as good" tools are buried in the scrap pile.

Threads accurately and cleanly cut, with the least expenditure of time and effort, are other reasons why these better Taps are favorites in the shop.

If you've used them before, you know just how good they are. If you haven't, send us your first order—we know you'll be back for more. They're carried in stock in our sales rooms in all large cities.

STEEL

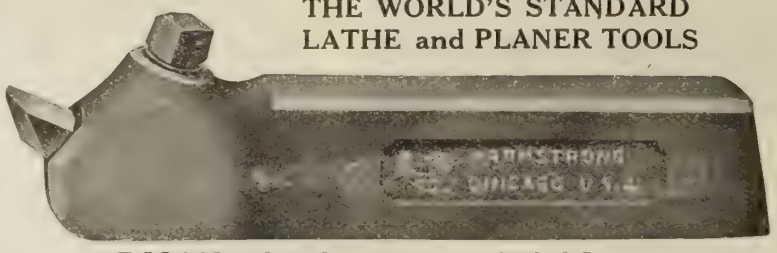
FROM what do we construct modern buildings, modern ships and modern bridges? STEEL. The same with pulleys. In the "American" one finds the ideal material combined with the experience and refinements of over twenty years.

Six million have been sold.

A book entitled "Getting Maximum Pulley Efficiency" shows in detail the reasons why; it will be sent at once on request.

The American Pulley Co.
Philadelphia, Pa.

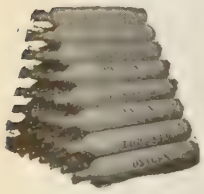


AMERICAN STEEL SPLIT PULLEYS

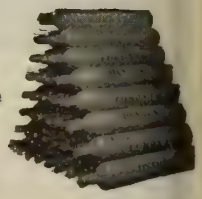
ARMSTRONG TOOL HOLDERS

Machine shops the world over, for more than a quarter of a century, have recognized Armstrong Lathe Tools to be by far the Best in lathe tool equipment.

Refuse to use imitations. Insist upon being supplied with "Armstrong."



THE WORLD'S STANDARD LATHE and PLANER TOOLS



By using Armstrong Tool Holders in your shop you will make one pound of High Speed Steel do the work of ten pounds in forged tools, save all forging and 70% of grinding.

Examine your files carefully each day for signs of wear.

The proper time to discard a file is when the teeth have become just a tiny bit "dull".

The slightest loss of keenness means reduced efficiency—and a trifling sum buys a new one.

Our famous five brands of files, specially hardened, stay keen and efficient for the longest possible time.

They are:

Kearney & Foot
Great Western

Nicholson File Company

Port Hope - Ontario

The Perfect Grip

An ordinary hammer will slice the head off a nail, because it gets a grip on the head and not on the nail. With the head off, it's all off.

Williams' perfectly balanced Hammers will grip the *body* of a nail and pull it, head and all, clear through a plank. All nails are trailers to Williams' hammers.

Heads on or heads off, for drive or pull, Williams' Superior Drop-Forged Hammers are the bosses in the nail world. Good workmen want them because they fit the hand, are perfectly balanced and are good all through.

Literature?

"I Wish I Had Fixed Those Belts Before The Rush Started"

Just as sure as "eggs is eggs," factories will be struck with a sudden batch of orders to fill starved store-shelves, and the orders will be marked RUSH.

If you neglect fixing up Belts on your machinery, and put off buying new ones where needed, you are going to get into trouble with the production end of your plant. Don't take chances; get fixed up NOW with—

This Belting made in all sizes, for the biggest mill on the continent to small machine Belts, in the littlest factory. Wet-proof, Dry-proof, Heat-proof, Cold-proof. For efficient transmission use "P.M.S" Belting.

Increase the Consumer's Interest

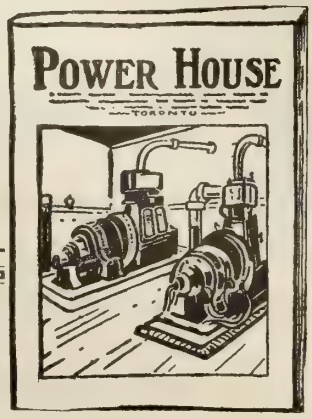
Create a Livelier Demand for Machine Shop, Power House and Foundry Equipment

ARE you manufacturing equipment for Machine Shops, Metal Working Plants, Power Plants and Foundries? Does the consumer know your products? Does he know their quality sufficiently to insist upon getting them when he places an order with his hardware dealer? Carefully weigh these questions. Then consider the advisability of reaching the consumer through the columns of MacLean Technical Newspapers. You can probably use one of the following group.

CANADIAN MACHINERY AND MANUFACTURING NEWS—issued weekly, serving the Canadian Machinery, iron, steel and general metal-working industries: it is read by the men who buy equipment, proprietors, purchasing agents and other executives: its editorial contents are authoritative and comprehensive.

POWER HOUSE—published twice a month, serving steam, electrical, water and gas power plants, in addition to refrigeration plants, in all parts of Canada. It, too, reaches the men who buy equipment; it, too, is the leading authority of the Dominion in things pertaining to its field.

CANADIAN FOUNDRYMAN AND METAL INDUSTRY NEWS—published monthly, rendering indispensable service to the grey iron, steel and non-ferrous foundries of the country. Proprietors, executives and foremen read it diligently.



You can awaken new interest in your products by advertising them to the consumer through MacLean Technical Newspapers. Write for complete information.

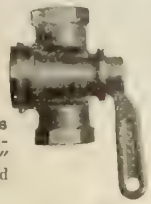
CLECO PRESSURE SEATED AIR VALVES

Style PO

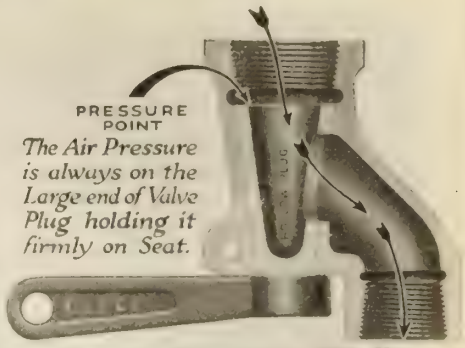
Style PO: Parallel Valve has "waste port" to bleed the air from hose after valve is shut off, sizes ¼" ⅜" ½" ¾" 1" 1¼" 1½" and 2" Standard Pipe Thread Inlets and Outlets.

Style A



Style A: 30-degree Angle Valve, sizes: ½" and ¾". Inlets and Outlets are Standard Pipe Thread.

Style RA: 90 degree Angle Valve sizes ¼" ⅜" ½" and ¾". Inlets and outlets are standard pipe thread.



Style RA

Styles A, RA and SL have waste-ports to bleed air from hose.

Style SL

Style SL: The inlets and outlets are the same size and in alignment. Sizes ¼" ⅜" ½" ¾" 1" 1¼", 1½" and 2" standard pipe thread.

The Valve That Improves With Use
Requires no attention after installation.

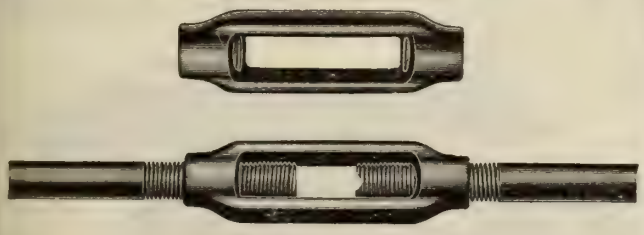
IN STOCK

Riveting Hammers, Chipping Hammers, Sand Rammers, Air Drills, Grinders, Corner Drills, Bowes Hose Couplings, Cleco Air Valves, etc.

Style FWL

Style F.W.L.: Four-way valve controls the supply and exhaust from both ends of a double acting piston. Sizes: ⅜" ½" ¾" and 1" outlets.

Style LW



Style LW: Three way valve sizes ½" ¾" and 1" Outlets standard thread.

Measuring the Walls of Cylindrical Forms

accurately is often an awkward and difficult job. That's where you need a Starrett No. 175 Inspector's Micrometer Caliper Gage. This gage makes determining the thickness of boilers, flues, tubing, drawn die work, etc., a quick and easy job, and is largely used for such work by U. S. Government Inspectors.

Furnished with two anvils, this gage is capable of measuring any dimension from 0 to 2 inches by thousandths of an inch. Equipped with Starrett micrometer lock nut and ratchet stop. A 1-inch Starrett Standard Gage Plug is supplied with this tool to facilitate accurate setting when the anvil for measuring from 1 to 2 inches is used.

Cylindrical walls are as easy to measure accurately as flat material if you use the Starrett No. 175 Inspector's Micrometer Caliper Gage.

Get full information about this and other new Starrett Tools in special Supplement to the Starrett Catalog No. 22 "3" Free copies of both supplement and catalog sent on request.

MANUFACTURING NEWS

VOL. XXVII, No. 12 MARCH 23, 1922

Executives Should Consider Grinding of Parts

Rapid Development of Grinding Machine—Greater Degree of Accuracy Possible—Type of Grinder Depends on Class of Work —Machine Parts Now Made of Harder Materials

By J. H. RODGERS

THE field of commercial grinding is becoming larger every day. Primarily intended for the reduction of tempered parts and for the correction of slight errors due to warping in hardening, the grinding machine, as an economic manufacturing precision tool, has established itself in the front ranks of production equipment in metal working industries. Work that formerly was taken care of on lathes, planers, millers, and other machine tools, has been turned over to the grinder, and the latter is performing the task at considerably less expense and producing a better quality of product.

Interchangeability has become more universal as a result of the development of grinding machinery, and accuracy, to-day, is qualified in millionths of an inch, where a few years ago thousandths were considered very close measurements. Not only is this true where very fine tools are the lines manufactured, but in every branch of industry the grinding machine in some form or other is proving itself one of the most useful, as well as one of the best time and money saving tools among the many metal working machines now in operation.

In the selection of a grinding machine many factors must be considered, as a machine suitable for work in the tool room, would, in many cases, be entirely unsatisfactory for producing parts on a quantity basis. The character of the work is the main essential. If the range of work is limited a specially constructed machine would probably be more suitable than if the class of work was varied.

The wider application of grinding equipment to general manufacturing has made possible the use of harder materials in machine parts that previously had to be avoided owing to the great difficulty of machining and necessity of subsequent hardening or heat treatment.

Grinding machines are rapidly approaching the semi and full-automatic stage. Precision work is now accom-

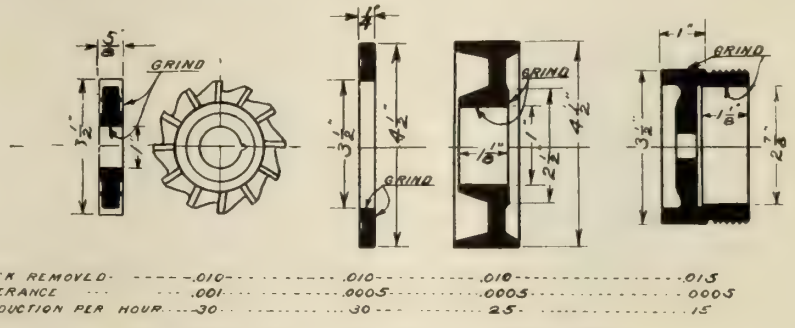

Fig. 1.—Examples of work done on 2 spindle machine.

Cuts and information by courtesy of the Bryant Chucking Grinder Co., of Springfield, Vt.

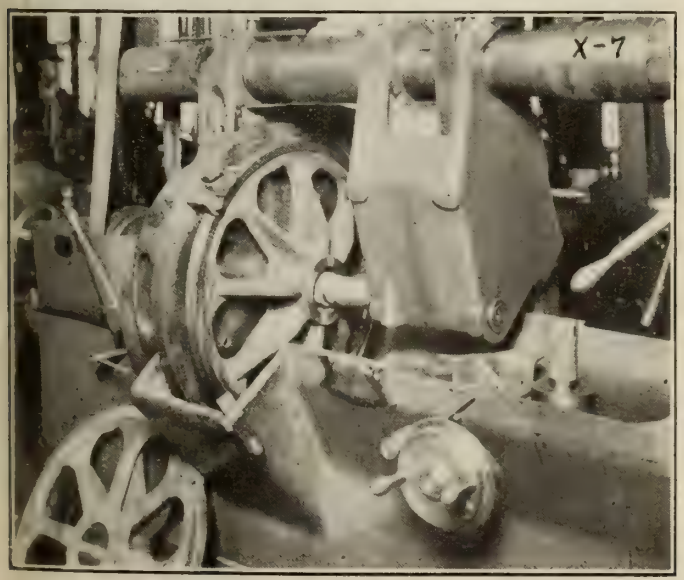

Fig. 2.—Grinding bore of gear shaper index wheel.

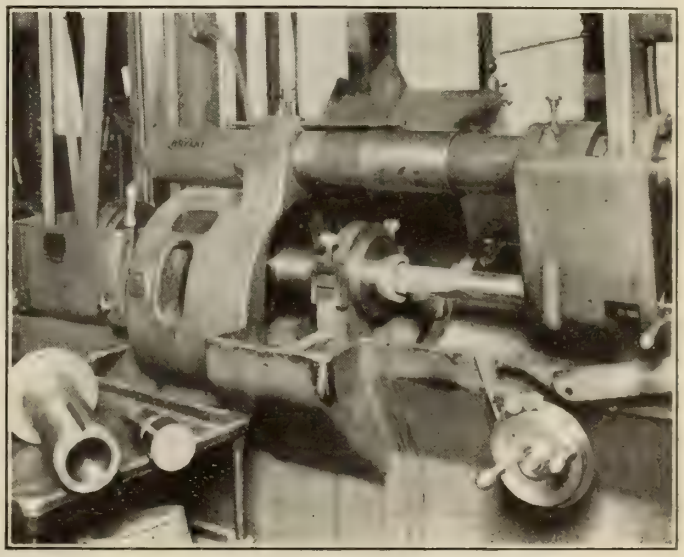

Fig. 4.—Example of deep hole grinding.

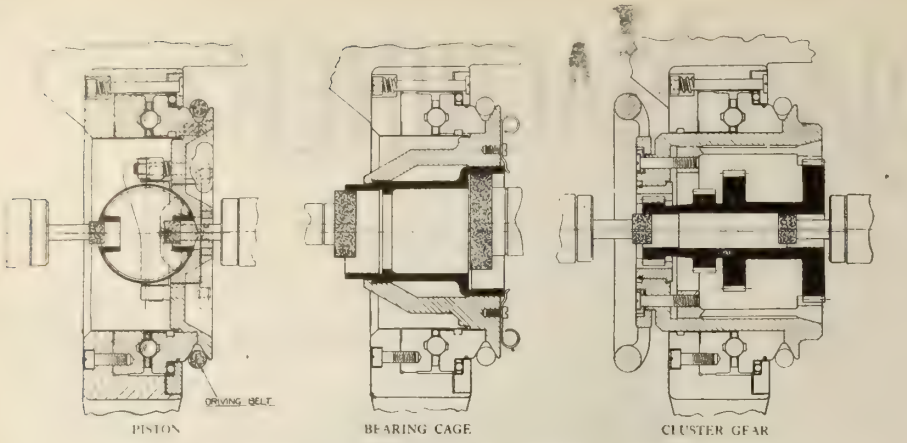

Fig. 6.—Showing work set up on two-spindle machine.

plished on parts where two wheels are operating on different portions of the one piece, thereby cutting the production time almost in half. The accompanying brief article describes a few examples of grinding that have been successfully accomplished.

Fig. 1 shows several examples of work ground on a two-spindle machine, one spindle working on the bore and the other facing the hub or end. The piece to the extreme right shows a part for the Rio Motor Co. The 2⅞ in. hole is finished and the 3½ in. outside diameter is ground with the larger wheel at the same chucking. Not only is the time of re-chucking saved, but finishing the two surfaces at the one setting insures their being absolutely concentric

The illustration Fig. 2 shows a large heavy piece which it is necessary to grind internally. This part is the lower index wheel or worm gear of the Fellows gear shaper. The rim of the work is set back against the face plate, the locating surface being previously ground on a surface grinder. The grinding wheel recommended for this work is a crystolon 24 grain, grade J, operating at 5,500 r. p. m. The size of the wheel is 3½ in. diameter by ¾ in. face. A Bryant No. 30 internal grinder is used for this operation, the production rate being approximately four pieces per hour, removing about .015 in. of stock to a tolerance of .0003 in.

It is becoming more and more a standard practice among automobile engine manufacturers to grind both the crank and wrist-pin holes in connecting rods. Fig. 3 shows a semi-automatic hole grinder working on this operation of grinding the wrist-pin hole in Franklin connecting rods. The rod is located from the crank-pin hole, which has been ground at a previous operation. This wrist-pin end is centred from the hole by a flat hand plug and clamped in position free from any strain. Removing .010 in. of stock to a tolerance of .0005 in., the production obtained is about 25 per hour. Morton alundum, grade L, grain 50 wheel is used, 1 in. by ⅝ in.

A good example of deep hole grinding is shown in Fig. 4. A quill is being ground internally on a special deep hole grinder. This machine was used extensively during the war for grinding airplane cylinders. One end of the quill is centered and driven by face plate on work spindle. The outer end is supported as shown in a steady rest. The part is made of chrome nickel steel, averaging .60 per cent. carbon. The hole is 2⅞ in. diameter and is ground to a depth of 10 in. Approximately .015 in. of the material is removed from the diameter and the tolerances are from .00025 in. to .0005 in. oversize. The production is about two holes per hour. The wheel used on this operation is alundum 2½ by ¾ inches, 38-36 grain, grade J, operating at a speed of 7,500 r. p. m. The work rotates at 200 r.p.m.

The view shown in Fig. 5 illustrates a machine grinding the bore of a Fellows gear shaper cutter. Previously the holes in these cutters were ground and lapped to size, but it has been found possible to eliminate the lapping operation, grinding to a tolerance of .0001 in. This operation is performed before the teeth are ground and accordingly the cutter is centered from the rough hole, being held on a magnetic chuck. Best results are obtained by using two wheels of different grade on the same spindle, one particularly adapted for roughing and the other for finishing. The wheel used for roughing is alundum, 38-50 grain, grade H. The finishing wheel is also alundum, 38-90 grain, grade J. It has been found that the mirror-like finish is produced by using a cutting lubricant

Controlling the Cost of Labor and Output

Getting Full Value From Workmen—Rating of Labor—Accurate Cost System—Material a Known Factor—Non-Productive Periods—Time Servers—Individual Job Records

By J. H. MOORE

HOW can I increase production? How can I prevent time loss? How can I obtain the actual time spent on every job? These three questions are of paramount importance to every executive, especially at the present time when they must stop all leaks in order to show a profit.

There are various time and labor saving devices and systems in operation throughout factories today, but for the purpose of this article we will consider only one. Before touching on the system itself, let us view the necessity of a close check on labor costs.

Any manufacturer would be highly indignant were he to see one of his employees walk into the main office, open up the safe, take out some money from the cash drawer, calmly place it in his pocket and walk out to some store and spend the pilfered cash. At first sight this appears a rediculous situation, but the same thing is happening in plants all over the world today, in as deliberate, but slightly different manner.

Instead of coming into the office and pilfering the cash, the worker is content to stay in the factory and take it away from the firm in the shape of lost time, that is, except you have close check on his activities. Were he to come to the office and steal the cash, for stealing it is, you would have him arrested. On the other hand you cannot bring him to a court of law for stealing your time, which you pay him for, but you can arrest his time-pilfering methods by insisting on his using some sort of a time and labor checking system.

Time, like any other commodity, is bought to be sold at a profit. You employ a man at so much an hour, expecting him to give you sixty minutes service for one hour's pay, but do you follow the matter up to see if you are securing full payment, or are you content to trust to the man's honor to turn in an honest day's work.

Human nature is much the same all the world over. Where you find one honest and conscientious worker, you will discover a dozen or more, who feel they are equally as honest, but their idea of a full day's work is nothing to boast about. The really honest worker does not object to his employer keeping track of his time, for he has nothing to fear. Therefore, to make sure that the dullards turn in full value for money received, you require some time and labor checking system.

One of the most important yet perplexing subjects has always been that of accurate costs. In rating the value of labor we must start at the cost, and what it returns in profit is based solely on what it has produced over and above its cost. An accurate cost system, irrespective of its style, must consider three basic principles as its foundation, viz., labor, material, and overhead expense, usually termed burden. We know, or at least should know, the cost of all material entering a product, therefore material can be said to be a known item of expense. It is purchased in specific quantities, so that the problem of keeping costs resolves itself to the keeping of simple records in the office purchase ledger.

Overhead expense is taken care of by the regular accounting methods, the rate depending upon the nature and size of the plant. But how about labor, or to put it in another way, job time?

Variable Factor

Labor is a most expensive item, and varies more than any other factor in business. When a plant owner buys labor, he is, or at least is supposed to be, paying for time, and what it produces. If a workman spends a non-productive hour, it will not show up on the books unless some method of checking is followed out. Nevertheless, the lost time is there, and it is the avoidance of such loss which should interest every plant manager.

To gain control of your labor costs, you must know exactly the extent of your production in return for your labor expense. In other words you must know productive from non-productive time. To do this you must have some system whereby an accurate record can be kept of the time spent by each employee on each job.

The value of having employees punch cards as they come and go from their work is now established. It is a rare exception where you do not see time clocks

of some kind installed for this purpose, but what happens after the worker rings in his time card? From practical experience in the shop, I draw this little word picture, with which many plant owners are no doubt familiar.

Around about 5.50 p.m. every night there is a glance at the clock, a wiping of the hands, a searching for time cards and pencils, then a lapse on the part of the workers into deep thought. Suddenly some one will say to his mate on the next machine, "Say Bill, did you notice when I started on that A 2 job." "Somewhere around 2 o'clock I think," comes back the reply, and down it goes as 2 p.m., irrespective of the actual starting time. Strange to say, (or is it strange?) all the cards total up to 10 hrs. actual time, but are they mythical hours, or productive hours? Common sense provides the correct answer.

Pencil Marks can be Altered

Let us go a step further with this shop picture. The cards reach the foreman before going up to the main office. On looking them over he discovers Bill Jones was 5 1-2 hrs. on the B 6 job. "That's too long," he mutters, "I'll speak to him about that," so with the aid of the little rubber tip on his pencil, he changes the figure to perhaps 3½ hrs. and adds two hours to general maintenance, in order to bring the grand total up to ten. Impossible? If any executive thinks so, let him study the matter

Inspector J. Jones Foreman P. L. Smith

Sample card used for daily job record.

closely, and he is due for a disagreeable surprise. Of course every foreman is not addicted to this habit, for which we are duly thankful, but so long as the danger and temptation exists, a certain percentage are bound to fall from grace. They feel they must protect themselves, and that Bill Jones is not going to get them up on the carpet owing to his slowness at times.

A job-time record-keeping system eliminates any such danger. It guarantees that every employee gives an account of his work. The foreman cannot change the records, the executive in the main office secures a true story of activity in the shop, and thus the deadwood is soon weeded out.

The time spent by the foreman looking over the cards as formerly, is cut down considerably, as they are all legible if stamped, so that the time saved in this way can be devoted to seeing that Bill Jones and other employees are doing their proper share of work.

If the foreman himself is to blame, the cards will show it, so that naturally he sees the workers do a fair day's work, in order that his production cards will show up to good advantage.

Suppose we have a department containing 20 men. This means that purchased labor for the week is 1,000 hours. Suppose at the end of the week, taking it for granted some record keeping system is installed, only 900 hours productive time shows on the cards, what then?

Must Explain Loss

Naturally the foreman must explain the loss of 100 hours, and in chasing up this loss, he may discover that the operator on machine No. 10 waited 15 minutes for material. Immediately he finds out who was responsible for this condition, and so on he goes, operation to operation, until he finds the cause.

Another workman may blame his machine for being out of order. Suppose this to be true, and imagine this has been happening week in and week out for some time. What is the answer? It means that the machine will be closely examined, and if it cannot be repaired satisfactorily, a new one will be installed in its place. Better spend a little money to stop a leak, than let a small amount of actual cash drop away every day, the amount of which will soon total up to the price of a new machine.

Rather than keep on pointing out benefits which accrue from proper job time recording, we will discuss briefly one system which has been adopted in many plants with good success. A recorder is arranged to receive cards, which when placed in position, are printed as regards the time of starting and stopping a job, simply by the pressing of a lever.

Depending upon the nature of the work, and the wishes of the management, one card for every job can be used, or a daily card covering all the work completed each day. For example Fig. 1 shows what is known as a daily cost card. As will be noted, the time started and stopped on each job is recorded, the elapsed time, the rate, the cost, the number of pieces, the order number, and the operation. Thus, at the end of the day the time clerk has a definite record of the workers' activities during the day.

As the card is self-explanatory, we will pass on to Fig. 2, which shows the style used when there is a card for every job. Many plants favor the latter method, this allowing them to keep all the cards on the one job together. It will be noted on this type, that we have the job number, the part number, date, name, what it's for, operation, quantity started, quantity finished number spoiled, the reason, when started and stopped, and the inspector and foreman's name. Thus, we have a very careful check on the piece all the way through.

Fig. 3 shows another form of card which has proved satisfactory, and in this case we have practically the same information in Fig. 1, but in somewhat different style. It is a question of arranging the card to suit the class of work, but the type shown at Fig. 2, is almost universal, and can be used on any product.

When using a system of this kind, racks should be provided to hold the job time cards, and every worker should be given a certain number. It should be the foreman's duty to see that these racks are kept supplied with cards, so that no one will be waiting to secure orders for the next job. The old story of looking for the foreman is thrown in the discard, for his presence is unnecessary, so far as handing out the next order is concerned. The machine operator knows he must account for every minute of his time, and he also realizes that he cannot waste time on any job, for it will show up on the card.

You get maximum efficiency with least effort. It does not matter whether you use a recorder which is spring or electrically driven, the principle is the same. The operator takes his card, places it in proper location, presses a lever, and a printed record is automatically recorded in the proper place. The recorder can be arranged and equipped with the regular hour and minute printing wheels, or with decimal minute wheels printing in tenths or hundredths, or in any period desired. Every recorder has in addition a wheel which prints in either the day of the week or the date of the month.

The time registered on the job time card is checked with the time clock card, so that immediately the cost clerk knows whether employee No. 23 has done a fair day's work or not. Every worker is his own time keeper, and helped by mechanical means, he cannot make an error. You take the pencil out of his hands, and give him instead a mechanical method of recording his activities. You prevent disputes between the foreman and men, you soon find out the intelligent workers, you prevent a false balance of cost records, you reduce the expense in the cost department, and you furnish a double check on the pay roll.

Practically every business office today has its check protector, and naturally feel more safe than they ever did before. Why? Simply because they know the figures on the check cannot be altered. The same principle applies to cost recording. Make sure you adopt a system which guarantees that the true story of the cost cannot be changed. Adopt such a policy, and you will be mastering a grave industrial leak.

Don't rub your greasy fingers on a piece of work that you are filing.

Increasing the Efficiency of Electric Motors

Use of Ball Bearings Proves Effective—Sliding Friction Reduced to the Minimum—Comparison of Different Types of Bearings—Permanency of Lubrication—Less Space Required

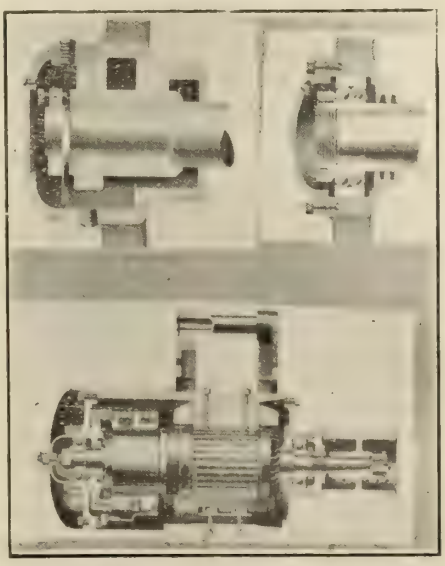
By R. H. CHADWICK

INDUSTRIAL operations are carried on for profit, and profit depends upon the difference between selling price and cost. This difference due to the events of the past few years, has been steadily decreasing—especially in the manufacture of electric machinery. For on one hand the cost of all raw material has been advancing as has also the cost of labor and the expense of marketing the product; on the other hand the manufacturers of electric machinery, because of keen competition in this line, have not deemed it expedient to advance their selling prices in proportion to the increased costs.

The service rendered by electric machinery produced by the various manufacturers is so nearly identical that no one company has considered it wise to take the initiative in marked advance of selling price. Such conditions might soon prove disastrous, and so each manufacturer has been endeavoring to incorporate in his machine a unique feature which will mark material improvement, thus inducing the prospective customer to pay an increased first cost and receive ultimate economy.

Many of the leading manufacturers, both on this continent and in Europe, have answered this question by incorporating ball bearings in the design of their standard equipment. No other single improvement has been made for many years, which has increased the ruggedness and economy of motors as much as ball bearings. The improvement has proven to be a marked selling advantage, and ball bearing equipment, because of its strong sales appeal, put motor selling on a more profitable plane.

For a number of years the desirability of using ball bearings on electric machinery, has been the subject of discussion by engineering societies, both in this country and in Europe, but this no longer proves to be a discussion, but has developed into a real commercial proposition.



Not only has the incorporation of ball bearings in motors and generators lessened the selling expense for the manufacturer, and allowed him to charge a higher price, but it also offered such economies to the users of these machines that the higher initial cost has been much over-balanced and additional profits made possible. In fact, progressive mill owners, mine superintendents, and shop managers all over the country, who are facing the same problems of advanced costs of material and labor, and are now forced to reduce to meet the present depression, are introducing better machinery, and to grasp every opportunity for completing a manufacturing operation in less time and at a decreased expense, and so they are specifying ball bearing equipment.

In order to obtain an idea of the advantages of the application of ball bearings to electric machinery, a series of questions were recently submitted to motor manufacturing engineers and users of ball bearings throughout the continent. A careful analysis from the data received, giving the tests, and experience of motor designers and users shows the following advantages in favor of ball bearings.

Maintained Air Gap

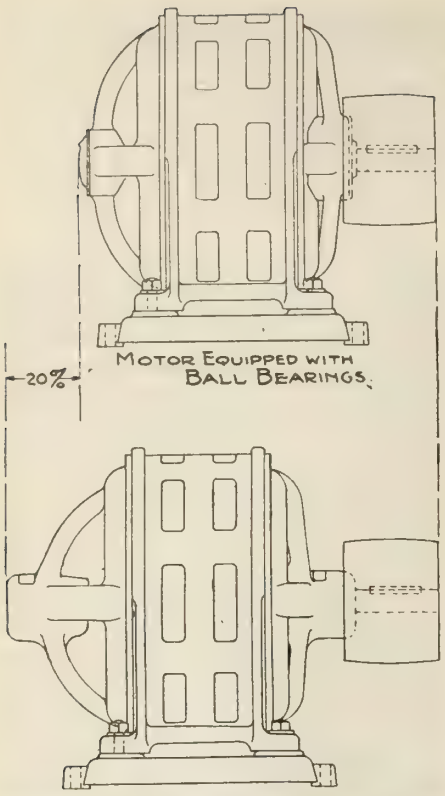
Among the principal advantages of ball bearings on motors, are their precision and freedom from wear, this being due to the fine limits maintained and the Swedish chrome alloy steel, thoroughly hardened, which is used in the manufacture of same. The bearing adjustment remaining constant keeps the rotor in the center of the magnetic field. This permits the motor manufacturer to employ air gaps with clearances so slight that they could not be considered on motors having any other type of bearing. On induction motors a close air gap is of vital importance in the improvement of the machine efficiency and power factor.

Chief among the difficulties with plain bearings is the fact that after a period of service the bearings wear down to an amount varying with the load and service conditions. If this wear continues, it will finally permit the armature to touch the pole pieces with resulting trouble—perhaps a stripped armature. In a ball bearing, hardened steel balls, roll on hardened steel raceways, thus sliding friction is practically eliminated and accuracy maintained.

Upper left—Bearing using ring or chain oiling system.
Upper right—Ball bearing chamber open at side.
Below—Axle lighting generator. Armature shaft mounted on H. B. ball bearings.

On axle driven generators used for railway car lighting, the bearings must maintain the air gap or a stripped armature results. Ball bearings have replaced plain bearings for this service, almost entirely because of the dependability attained. Records of 200,000 car miles, where ball bearings are used, have become common, in spite of the frequently excessive tension of the belt. The shock and distorting action of the shaft due to crossovers, switch frogs, and uneven tracks, the snap of the generator belt when flying ballast is picked up and passes between the belt and the pulley, all deflect the armature shaft. It is found the self-aligning ball bearings accept these shaft deflections without binding or wear.

Improved Commutation



The fact that ball bearing housings are fitted with felt rings, and are sealed so as to prevent the possible escape of lubricant and also prevent the intrusion of dirt or grit into the bearings, keeps the commutator clean. Commutators are thus protected against a conducting mixture of dust and oil and good commutation is maintained. Precision and durability of bearing setting also insure better commutation.

Freedom from sparks from the commutator in flour mills, coal mines, textile mills, woodworking plants or wherever there is combustible dust, reduces the possible danger of ignition or explosion, thereby materially decreasing the fire and accident hazard.

Comparative Efficiency

On motors in which the shaft is subject principally to rotating action (torquet), bearing friction is a very small percentage of the motor losses. This is the case in direct coupled units, centrifugal pumps, motor generator sets, etc. The bearings carry little if anything, in excess of the weight of the rotor, therefore, pressure between shaft and bearing lining is inconsiderable and bearing friction is a minimum.

Where the motor shaft is subject to bending action, however, bearing friction becomes an important consideration. This is the case with belt and

Showing gain of floor space by use of ball bearings.

gear drive motors. The bearings are subject to severe, bending, pounding or shock strains, especially at the driving end. Ball bearings in this instance show a decided saving over plain bearings. This is due to the fact that in ball bearings the friction is practically constant, over a wide range of pressures, and because rolling is substituted for the rubbing action of plain bearings.

Compactness

Compactness is required in conditions usually found in general industrial applications for induction, and direct current motors. To get this feature of compactness, motor manufacturers develop the greatest possible horsepower from a given size of motor frame. The reduced size per horse power capacity gives the greatest driving power in limited space conditions. The length of motor bearings affects the question of compactness to an important degree. Babbitt bearings are usually designed with the box length two and one half to three times the diameter of the shaft which they support.

Contrasted with this, the length of bearings along the shaft usually is not over one-third of the shaft diameter. Surrounding the bearing is the lubrication chamber, which at its outside limits is one-half or one-third shorter along the shaft than the plain bearing for the same motor, with the result that the overall length of motors can be reduced 10 p.c. to 27 p.c. by the employment of ball bearings. Where a consideration of aisle room, floor space, machine arrangement, etc., is necessary, a ball bearing motor goes a long way towards solving the problem, as shown in the following table:

PLAIN DIRECT CURRENT MOTORS

SIZE of Motor H. P.	MOTOR LENGTH OVERALL Sleeve bearing Motor in inches	Ball bearing Motor in inches	REDUCTION in length per cent.
5	26-1/8"	23"	12
6	26-7/8"	24 1/4"	9.8
7	31-11/16"	26"	18
8	35-1/2"	29 3/4"	16.2
9	38-7/8"	32 1/8"	17.4
10	41-9/16"	34 1/4"	17.6
11	45-7/8"	37-7/16"	18.4
12	49-7/8"	38 3/4"	22.4

INTERPOLE MOTORS

Motor	MOTOR LENGTH OVERALL Ring Oiling Bearing Motor Inches	Ball Bearing Motor Inches	Reduction in length Per Cent.
1/2"	18-7/8"	16-1/4"	13.9
1	20-15/16"	18"	14
2	23-7/16"	19-7/16"	17
3	25-1/8"	19-5/8"	21.8
5	28-1/8"	22-1/8"	21.2
7 1/2	33"	25-9/16"	22.6
10	37"	28-3/4"	22.3

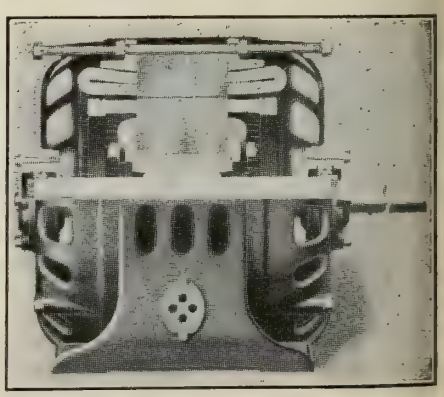
20	45-1/2"	33-3/16"	27.1
25	45-5/8"	37-3/4"	17.3
30	51-3/8"	38-1/16"	26
40	53-3/16"	41-5/8"	22.2
50	57-1/8"	42-13/16"	25

Simplicity And Cleanliness

The use of ball bearings reduces the head construction to its simplest terms. Instead of oil rings, chains, wicks, waste packing or other devices, which are required for plain bearings motors, ball bearings require no oiling devices other than the ball bearing itself, which are, in themselves, positive self-lubricators. Instead of necessitating frequent inspection of the bearings, renewal of the lubricant, and possibly occasionally rebabbitting, ball bearing motors require no attention other than the periodic lubrication; the length of time between inspections being from one week to six months, depending entirely upon the nature of the service. Ball bearing motors are clean. The bearings are encased within heads with sealing grooves on each side of the bearing, preventing the leakage of lubricant. With this protection, dripping or leaking of oil is eliminated and there is no danger of goods becoming soiled or contaminated with oil from this source.

Gear Drive Motors

Where gear drive is used, ball bearings on electric motors are of particular advantage. In order that gears shall run smoothly and quietly, the proper distance between pinion and gear centres must be maintained. It is a fact that noisy chattering gears may be caused by wear having taken place in the bearings supporting the gears. After long service with this type of drive, ball bearings show no appreciable wear, and consequently the gears mesh properly, giving longer and better service.



Plain bearings must be designed so that the pressures are well under the limit for the corresponding speed of the bearing. To reduce unit pressure in the bearing surfaces it is necessary to increase the rubbing area. This may be done in either of two ways. First by increasing the journal length. This, of course, offers the disadvantage of increased floor space required by the motor, and where compactness is a desirable feature this is a serious handicap. Second, by increasing the shaft diameter. Increasing the diameter, increases in direct ratio the speed of the rubbing surfaces, which should be kept as low as possible, because each increase of rubbing speed directly increases the likelihood of hot bearings. Larger shafts also mean heavier and more costly motors.

Whether, therefore, the bearing length or the shaft diameter be increased, the plain bearing is confronted with positive limitations. Ball bearings are designed for high speeds and heavy loads. The housings are short, and the motor on which they are used may be made very compact. Because of the compact construction the distance between the bearing and pinion is reduced, hence the overhung load on the bearing is proportionately reduced.

Ball Bearings on Axle Generators

Ball bearings are now used almost exclusively on axle driven generators as used on railways. A few years ago these machines were equipped with plain bearings. The service is so severe, however, and the attention that can be given is so small, that ball bearings have proved to be the only equipment that will "stand up." The generators are exposed to snow and ice, heat, dirt, and water, the jolts and shocks of passing crossovers and switches, and the continual jar of heavy track suspension. These conditions all play havoc with the plain bearing generators. The testimony of a superintendent of inspection of one of the largest railroads is eloquent with the advantages of ball bearings on these generators. He says "The cost of generator maintenance has been reduced on coaches 66 p.c., on diners 46 p.c; we have never had a hot bearing; have not lost any fields or armatures, the inside of the generator is dry, and we have no trouble due to grounds or short circuits." This is typical service where self-aligning ball bearings are used.

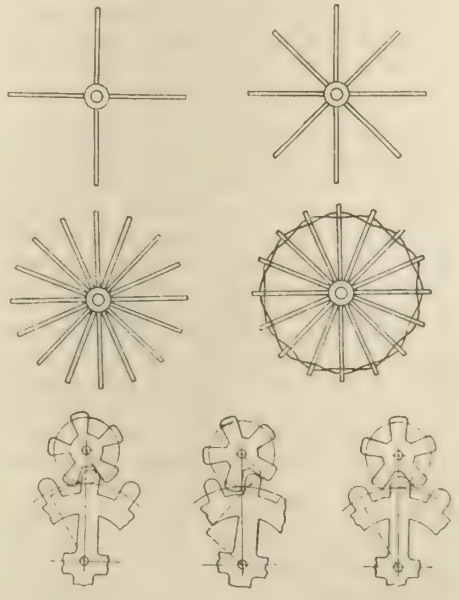
A New Form of Toothed Gearing

Radical Departure From General Practice—Great Flexibility Provided by Small Rollers—Adaptability to Modern Requirements—Tooth Forms Compared—This Type Practically Noiseless

By W. RUS. DARLING

THE PROBLEMS of power transmission have occupied the minds of many succeeding generations of engineers since Archimedes discovered the properties of the lever, gave unlimited extent to the notation of numbers, and founded the method of indivisibles or exhaustions which led up to the finest discoveries in geometry, and some of the greatest modern inventions. Following Archimedes, Appolonius of Perga, who was the first to derive the conic sections from a single cone, Pappus, Diocles and Nicomedes, who invented some of the higher curves, even Diophantus, who gave us the characters used in algebra, all helped towards the determination of that little curved line which encloses the form of a modern gear wheel tooth.



The higher geometrical science was originally applied to astronomical research, and enabled Aristarcus to expand immensely the conception of the solar system. By it Hipparchus sought to explain the apparent inequalities in the motion of the celestial bodies by the hypothesis of eccentrics and epicyles. Then mechanicians naturally followed the discoveries of the great men of the Alexandrian school, and devised eccentric, elliptical, and planetary gears. From the same geometrical sources there came later square and triangular gears, and other less familiar variable speed devices.

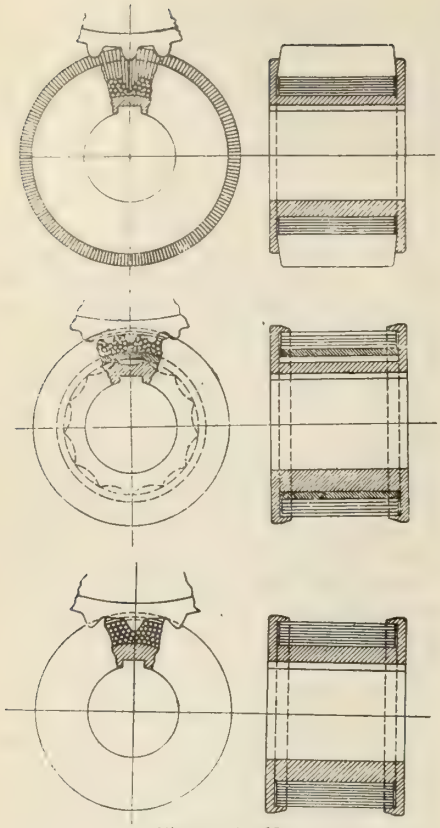
It is commonly supposed that the greatest mechanical discoveries are the result of chance that the most celebrated mechanicians had no theoretical knowledge and that even famous mathematicians have failed when they attempted to put their ideas into practice. It is no doubt true that chance sometimes unfolds important inventions, and that useful results do not always follow the laborious investigations of the theorist; but it is necessary for this that the productive causes be of the very simplest kind. The chance mixture of some substances gave birth to important chemical combinations; two convex lenses, placed parallel to each other at a certain distance and directed to a distant point, indicated the principle of the telescope.

The First Gear

History tells us that the first gear wheel was composed of flat pieces of wood, arranged in the form of a cross, Fig. 1, which were made slightly longer in one wheel of a pair. This was not for the purpose of modifying speed or power, but to ensure engagement. Subsequent developments of this idea extending over centuries are illustrated in Figs. 2, 3, and 4. In the latter the extremities of the arms are stiffened by binding, and indicate the first approach to the modern toothed wheel. Previous to 1674 teeth were of no particular scientific form, but were merely more or less regular excrescences on the rims of the wheel and pinion. About that time Roemer, a Danish mechanician, first applied the epicycloidal curve with the object of securing uniformity of pressure and velocity.

Within the last 50 years makers of clocks, watches, chronometers and mathematical instruments shaped their wheel teeth to please the eye drawing them to an enlarged scale for better discernment then reducing them to the required size. Lancashire makers of watch wheels used the bay leaf as a pattern. It was not until the works of Camus were translated from the French that wheel teeth began to take a definite shape, and engineers and others realized that tooth designing was a science rather than an art and that only by following certain basic principles could they get uniform velocity, durability, and efficiency in their machines. Camus pointed out some of the limitations in toothed gears, for example, that pinions of a certain number of teeth were unsuitable for working with particular spur wheels, on account of the line of pressure being either outside or inside the pitch circle, Figs. 5, 6, and 7. In this connection it has long been considered unwise to have less than 14 teeth in any pinion, and in present-day work, whenever high ratios are required, involving pinions of small diameter, the teeth are made to a fine pitch with a corresponding widening of the face.

Figs. 1 to 7.



Tooth Pressure

This brings us down to modern times and the question of tooth pressures, which still awaits the final answer. It should be easy to determine, even in the laboratory, what pressures can be economically withstood by the various metals available for wheel teeth; but the great difficulty of maintaining, under certain conditions, the contact of wheel and pinion teeth along the whole face must be recognized, and also the possibility of intermittent point contact provided for in the design and material.

In the case of reduction gears fo marine turbines, several devices have been tried, or proposed, for imparting flexibility and compensating inaccuracies of alignment and contact, but these have shown, naturally, better results in the testing department than in actual service. In so elastic a structure as a ship, no land trials can adequately indicate the behaviour of her machinery in heavy weather at sea. Even the most careful loading and trimming of cargo will leave the machinery in a different condition from that which prevails when running light. In a heavy sea there is a constant change of conditions, of torque, of alignment, of gear contacts, and of tooth pressures and it is not to be wondered at if heavily loaded gears wear more rapidly in heavy weather.

It is not proposed to make detailed mention of the best-known devices for fighting these evils but some of the less familiar propositions may be of interest. From Holland comes the proposal to subject the pinion blank to the torsion at which it is expected to work when in service, and to retain it in that condition while the teeth are being cut. A special machine has been devised for this purpose, and while the idea seems practicable, it appears, at the best, to provide only for mean conditions. In the United States of America it was discovered that pinions which had lain in the store for some months before being fitted into place had become so much distorted that they had to be removed, and the teeth recut, after a brief and noisy trial run. This led to the suggestion that certain parts of machinery should be laid aside in a rough state for some time before machining, so as to get rid of internal stresses. A very sensible practice adopted in machine-tool works in Germany reminds one that more thought should be given to the prevention of gear troubles rather than

Paper read before the Institute of Engineers and Shipbuilders in Scotland.

Figs. 8 to 13.

to their cure. This practice is to balance all rotating parts, and, according to report, it materially reduces the noise and vibration usually ascribed to other causes.

If inaccuracies, either in the form of teeth, alignment, or balancing of parts, were the sole cause of power transmission troubles, there would be no excuse for their continued existence, but there are, and always will be, certain varying conditions on land and sea which must be conquered. To overcome these varying conditions, it may be necessary to revise some of the basic theories, a to steer clear entirely of makeshifts and half-measures. A theory is nothing else but a regular union, or methodical and connected arrangement, of all the facts relative to a certain natural or artificial effect; facts which are obtained by true experience. If a theory is perfect, and the product perfect, the resultant effect should be perfect. The tangible elements, being subject to the five senses, may be easily dealt with and eliminated, and with imperfect results before us the theory must bear the blame.

I have endeavored to outline the combination of sciences from which were evolved the modern wheel and pinion, but the new gear which I now propose to introduce comprises an element which, to the best of my knowledge, has never before been applied to practical mechanics. Before embarking upon any radical change in a time-honored theory or practice, it is well to investigate their origin and development, and determine whether the justification is to be found in an inherent or an incidental deficiency.

Figs. 8 to 19 show how the new Autopitch Gear developed in the mind of the inventor, the first form consisting of a wheel body with loose pieces of thin plate fitted close together round the rim, forming, as it were, a regularly laminated ring in the position usually occupied by teeth and their corresponding spaces. It may be interesting to note how this idea originated. Having arrived at the conclusion that the old theories were unlikely ever to produce a gear which would in its own composition, cope with the varying conditions of wear, torque, alignment, expansion, etc., and that some of these conditions were natural and therefore permanent, the following list was made out to indicate requirements of a perfect gear:—

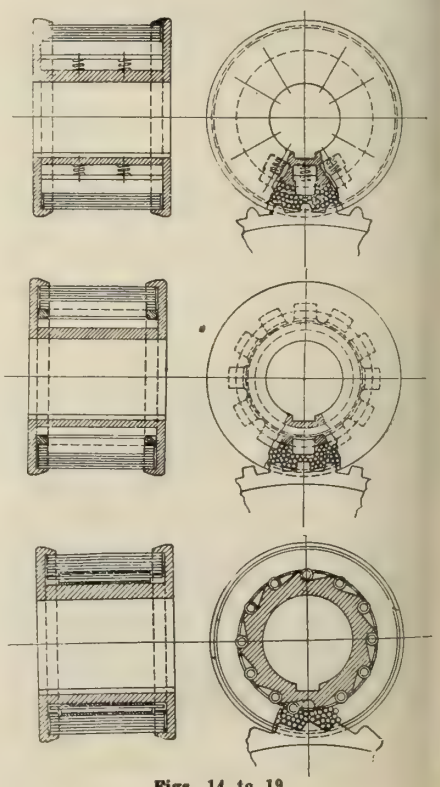
Strength, sufficient to ensure safety.

Durability, unlimited.

Adaptability, to all possible variation of conditions.

Elasticity, sufficient to absorb unavoidable vibrations of other parts.

Noiselessness, approaching to silence.



Economy, both in cost of production and in power.

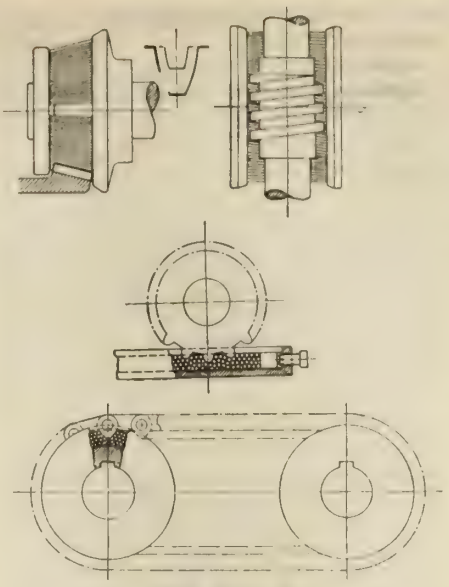
The first requirement, strength, seemed to be a matter of design plus material, the second, durability, of material plus design; the third, adaptability, seemed to lend itself less to ordinary methods of solution, and was set aside for a deeper analysis; the fourth, elasticity, seemed to depend on material plus design plus mounting; the fifth, noiselessness, would appear to be covered by the fourth plus workmanship; and the sixth, economy, may be accepted as secured by the realization of the other five.

On looking over this list it was apparent that the third requirement would be most difficult to fulfil, all the others being within the scope of modern knowledge and practice. With the time-honoured principle of the wheel and pinion still guiding the mind, a careful review of the reasons why this principle had failed to produce the desired adaptability, led to a concentration of thought on the pinion. Any trouble with the larger wheel of a pair was traced to the pinions which drive them, and it was then concluded that the solution of the problem might be found in a pinion which would have no pitch or form of teeth except that imparted to it by the engaging wheel. In other words, every driven wheel should be its own odontagraph. Simple minds mould their ideas from simple patterns, and, in this instance, having come to the conclusion above stated, the next step was to find some simple basic element or principle in nature, which, when viewed in the light of centuries of thought, experience and application, might point some untrodden way to the desired end.

The old mill wheel, with its continuous stream of water "gearing" into it, suggested possibilities. The mill stream adapts itself to almost any conceivable variation of a nature corresponding with those to be met with in mechanical gears. If the mill stream could be rolled up in a circle of suitable diameter, and provided with a shaft and bearings, it would form a pinion of the required adaptability. The absurdity is, of course, apparent, but in search for a new theory, apparent absurdities must be fully considered. And this same apparent absurdity is one of the most familiar features of nature; the feature which makes it necessary to build ships instead of railways. By the same method of reasoning the earth is revealed as a pinion, in constant motion, which, given the outside connection, might drive the universe. In the earth as a whole there is the embodiment of the idea of a mill stream revolving continuously round an axis. But in building up a theory the "methodical arrangement of facts" must be complete. Imagine a paddle-steamer in a fixed position relative to the motion of the earth, and the wheels driven by the water revolving with the earth, and you have the idea of the mill stream mounted on an axis. Being in possession of a theory which appears to be sound, it remains to be seen whether it can be applied within the limitations of known or achievable practice.

It is probable that machine-cut teeth are not always correctly shaped, although the machines ensure the equality of their pitch. The bearing between opposing teeth may be only at a point, or points, instead of on a line the full width of the wheel. Even this line contact, when acquired, is not a mechanical ideal. Teeth slide as well as roll, and concentrated pressure and friction are, therefore, of great importance, and it is only the high quality of the material available that enables thousands of horse-power to be transmitted through

Figs. 14 to 19.



one, two, or three lines of contact of one, two, or three feet lengths.

The value of the oil film and its existence between the engaging teeth are apparently accepted by authorities on gearing, and I sincerely hope that the acceptance is justifiable. If this film of oil is actually constant, it must be concluded that the pressure, the wear, and the transmission, are all effected through the medium of that oil film. It is estimated that in modern high-speed gears, the period of contact is about one-thousandth of a second, and from that fact is deduced the retention of the oil film.

From the foregoing it may be reasoned that the thicker the film the better, and, to carry this reasoning to its logical end, if the teeth of one wheel were eliminated and only the oil left, the theory of the endless mill-stream and the earth-driven paddle-wheel would be realized in practice. Absurd again, of course, but the question resolves itself into one of degree. How near can one get to a continuous oil film? The fluidity of oil makes it impossible to retain it in the form of a pinion rim of sufficient thickness to engage the teeth of the spur, so something else must be considered. If the oil is solidified the effect is no better, because, even if the radial forces suspended action, one revolution of the pinion would give it the impression of the spur teeth and destroy the continuity aimed at.

Reverting to the rational forms and materials of gear teeth, the finer the pitch the closer together, and therefore more nearly continuous, become the successive films of oil. If, however, the teeth are made too fine to carry the load, all the advantage would be lost, and it must be concluded, for the present at least, that the continuous film is impossible in practice; but there is an element which has not yet been considered. It is neither a fluid nor a solid, and yet possesses something of the nature of both. It is sometimes called a semi-fluid, and perhaps the only familiar form of it is to be found in balls. If a number of balls are poured into a vessel they will find a common level; if run out on a table they will behave much like water.

A less familiar form, perhaps, found in rollers, and here is an element which can only flow in two opposite directions. It is this fact, this limitation, which enables it to be harnessed in the form of an endless mill-stream within the compass of an ordinary pinion, Figs. 8 to 19. These figures show how this semi-fluid can be controlled and kept in its appointed place. The density of the element may be varied by having more or less rollers in a given space, and each roller being supported by all the others; their individual diameter does not materially affect their strength as a combination, which, in fact, forms one solid "fluid" tooth, equal in thickness to almost the circumference of the pinion.

Figs. 20 to 24.

Reverting to the "absurd" proposition of a continuous oil film it may be seen how nearly approach has been made to its realization. It is at once apparent that each roller provides a line of contact with the engaging wheel tooth, so that, instead of one line of contact per tooth, there is a number varying with the depth of gear mesh. Further, each roller has a film of oil over its entire length and circumference, therefore, there is actually that continuous oil film which was previously thought absurd. Not only that, the metal-roller element upon which the film is built is almost as fluid as the oil itself.

Having now completed a brief and rugged analysis of the theory and construction of a pinion designed to fulfil certain requirements, more particularly that of adaptability to varying conditions, there remains to be set forth, in a few words, its application to power transmission and the extent to which it meets those requirements. It may be easily seen that a pinion of this construction is able to accommodate itself to any straight tooth in a wheel, and will continue to do so until the tooth is entirely worn away. It is, therefore, independent of the contour and thickness of the tooth. Also, the tooth may engage with it at any point of its circumference, and it is thus independent of pitch. These facts indicate the elimination of geometrically designed teeth as a necessity, and also, that irregularity of pitch and missing teeth will not interfere with smooth and continuous running. Further, there are no tooth clearances, and therefore no backlash. Other irregularities are provided for in the fact that the rollers are free to incline in either direction across the face. The alignment may be faulty, parts may expand or contract, the foundations may warp and twist, but the little rollers will cling to the teeth of the wheel till it is ready for the scrap heap.

It is, perhaps, at sea with double-reduction gears and turbines that "varying conditions" are most pronounced and in this connection I will at this point in roduce some notes of an expert.

Some Notes on Behavior

"In vessels fitted with single-reduction gearing, the teeth should not suffer from the 'shock' forces which break or tend to break propeller blades, as the teeth are sufficiently strong to safely transmit the forces to the turbine; by so doing the speed of the turbine rotors is reduced, or may even cause them to stop or reverse when the forces tending to break the propeller are great. By this action the single-geared turbine acts as a cushion to the teeth, and it is for this reason that there are many successful steamers sailing today with this type of gear. But in the case of the double-reduction geared turbine this would not be the case, as the secondary pinion spindle carries the heavy primary gear wheels, which are virtually fly-wheels humming at between 500 and 600 revolutions per minute—the effect of which is to lock and damage the teeth when the propeller blades are breaking or tending to break.

"As the section at the root of a tooth on the main gear wheel of, say 4 feet 6 inches radius is very small when compared to the section of a propeller blade at 4 feet 6 inches of a 400-feet cargo steamer, and although there is about a three-tooth section in contact, it is only natural to assume that when destructive forces are tending to break the propeller blades the teeth will give way instead. The second-reduction pinion with helical teeth requires a slight fore and aft play, which becomes a fore and aft shooting of pinions and spindle, upon its well-oiled bearings, when the vessel is pitching, rolling, and butting into the waves."

It will be readily understood that the fore and aft shooting of the pinions referred to in these notes might have a very serious effect on the gear, and in the case noted it was so severe that every alternate five teeth in the main wheels were damaged by the impact. This effect was found to have its cause in the use of helical teeth, the pinions being shot to and fro by the action of the inclined planes in motion. This end-play had increased to ⅝ inch in the case cited.

Helical gears were first suggested by Dr. Hook, of Cambridge, with the object of obtaining continuity of engagement and smoothness of action; but, in cases like that cited, these virtues are not necessarily present. From what has been said of the new gear it will be gathered that these objects are expected to be gained with simple straight teeth; it has been claimed that the Autopitch pinion will mesh accurately with any straight tooth of whatever shape or thickness, but there are, no doubt, certain forms which will give better results than others. This presents a problem more difficult to solve than that of the pinion itself. In most of the trials carried out existing wheel patterns have been used, but it is intended to make experiments with teeth of various forms, and to compare results

Owing to the adaptable nature of the pinion tooth, clearances are unnecessary, and the periphery of the pinion may be fitted right down to the root of the wheel tooth, thus taking advantage of all the available surface contact.

In cases where existing tooth forms are used, it is neither necessary nor advisable to fit the periphery of the pinion beyond the normal pitch circle. Wheel teeth designed to gear with this pinion should not be more than half the radial length of standard teeth, and may be less. This is a point of some importance, as, assuming the thickness to be the same, the tooth will be correspondingly stronger. It also opens up the question of pitch, but the details are too obvious for inclusion here.

Some Forms of Teeth

Figs. 8 to 20 indicate some possible forms of teeth which may be used with this pinion, but further investigation and experiment will be necessary before the best form is determined. In Fig. 20 the light lines indicate the existing standard tooth and the heavy lines the proposed tooth. The measure of adaptability secured by this new form of gear wheel permits of its being used with bevels, worms, racks, and toothed chains, and several wheels with differing tooth pitches may be driven by one pinion. Figs. 21 to 24 will render a verbal explanation unnecessary in connection with these applications.

In conclusion, a brief review of the requirements for a perfect gear and the extent to which they have been met may now be given.

The first requirement was strength, and in the new pinion there is one almost continuous tooth, composed of hard-steel wires of, say, 14 W. G., the power being transmitted by as many of these as circumstances require. The tooth of the engaging wheel is, say, half the radial length and the same thickness, and is, therefore, four times the strength of a standard tooth. It is to be noted, further, that the load is distributed over the entire surface of the tooth in full gear. So much for strength.

Unlimited durability is, perhaps, too much to ask, but in theory at least it is nearly approached. The only part of the pinion subjected to frictional motion, and therefore to wear, is the rollers. These may not only be of a very lasting material, but their combined superficial area is very considerable, and the wear is distributed over the whole of that area. Further, the rollers may wear a great deal before the mass loses the density necessary to prevent slip. Even then, the slip would appear gradually and could be corrected at the first stoppage of the machine. Without removing the pinion a few new rollers can be dropped into place as easily as dropping oil, and the pinion is thus gradually renewed. The teeth of the engaging wheel will only cease to work when they cease to exist.

The question of adaptability has already been dealt with at some length, and I will only add that experiments have been carried out on wheels with broken and missing teeth, unequally worn teeth, bent shafts, wheels eccentrically and obliquely mounted, and imperfect alignment of parts without disclosing any undesirable effects.

With reference to elasticity, this is covered, for the most part, by the previous requirement, but it may be added that a mass of thin rollers with their continuous film of oil is expected to provide all the elasticity necessary. When the pinion is stationary the rollers settle down into a dead mass, but in motion the radial forces give them life, so to speak, and increase their elasticity as a whole.

Noiselessness is a very desirable quality in gears, and it may be gathered from the nature of the new pinion that any sound caused by it must be different from that of other types. All noise has its origin in vibration, and when one is absent so also is the other. Any of the new pinions which have been fitted make a sound like a stream flowing over a pebbly bed, and it decreases with increase of power.

There remains but the question of efficiency or economy of power, and, at the moment, I am unable to give any figures. The pinions in use so far have been fitted for the purpose of surmounting difficulties which had previously seemed insuperable, and have proved entirely successful. In some cases it was required to engage and disengage the gears frequently while the machine was running, and this could not be done by sliding the teeth into mesh. Pinions of the new type may be moved into gear instantaneously or gradually while revolving at any speed. This is done regularly at present at a speed of 2,000 revolutions per minute without shock or danger of any kind. This fact appears to indicate adaptability elasticity, and efficiency.

In bringing this new form of gear to your notice I have attempted to indicate a departure from the beaten track in the realm of power transmission.

EXECUTIVES SHOULD CONSIDER GRINDING OF PARTS

(Continued from page 18)

and coolant composed of kerosene mixed with a slight amount of light machinery oil.

Fig. 6 shows three special work holding fixtures used in connection with a double spindle grinder where the work is chucked in a central head, the spindle heads being located at either end of the bed. This machine grinds simultaneously two holes in the opposite ends or sides of such parts as hollow shafts, bearing cages, wrist-pin holes in pistons, etc. Both wheels work in unison and are advanced and withdrawn and likewise swung clear of the work at one motion of the pilot wheel. Grinding coinciding holes in this way, at the one setting of the work, insures accurate alignment of the ground surfaces, and in the case of pistons, brings the axis of the holes square with the outer surface.

INCREASING EFFICIENCY OF ELECTRIC MOTORS

(Continued from page 22)

The Lubrication Problem

Ball bearings offer the motor user one solution of his lubrication problem. The bearings are contained within simply constructed bearing head brackets, with liberal lubricating chambers, which are sealed on both sides and by end caps. These end caps are fitted close to the motor shaft, and are provided with felt retaining washers, which make it practically proof against leakage of lubricant as well as the intrusion of moisture, dust, lint, grit, or other foreign substances from without.

Ball bearings are positive self-lubricators. The ball spacer or retainer is of such construction that the bearings are open at the sides, thereby giving free circulation of the lubricant in the ball paths. Oil rings, chains, or similar rotating oiling devices are done away with entirely, and positive thorough and uniform lubrication is assured. It will be readily appreciated from the use of ball bearings on motors that: 1. They eliminate the frequent troublesome inspection of plain bearings—the user need not concern himself heretofore about the possibility of oil rings sticking. 2. Motors equipped with ball bearings are free from the nuisance and dirty conditions caused by creeping oil and dust around the bearing heads. Frozen bearings due to oil or lint, or draining of the oil reservoirs are practically eliminated.

Security against such conditions in many instances is worth the cost of the motor, and is particularly valuable in textile mills, flour mills, woodworking plants, or other places where dripping oil, adds to the fire hazard, or is ruinous to stock in process.

Briefly summarizing, the economies offered by ball bearings, are:—

(A) Smaller gaps permissible, because they will not wear down as plain bearings do. This gives an improved power factor for induction motors.

(B) Danger of armature touching the pole pieces is eliminated.

(C) Leakage of oil is prevented. Thus oil cannot drip onto the commutator, or oily dirt collect, causing flashovers.

(D) Overall length decreased from 10 to 20 p.c., resulting in a more compact motor.

(E) Longer period between motor inspection and lubrication required—once in six months against once in two weeks, with plain bearings.

(F) Fewer repairs and decreased maintenance cost.

(G) Improved motor commutation.

(H) Improved efficiency, because of reduction in bearing losses.

Don't strike a piece of hardened steel with a hammer.

Don't use the bed of the planer for a tool chest.

News From the Welding Field

Commercial Welding on High Pressure Boilers

Eliminate Guess Work—Weekly Test of Operator's Skill and Progress—Choice of Gas or Electric Process for Certain Classes of Work—Best Method of Applying Patches

By EDWARD H. HEIDEL

BOILER welding requires fusion of metals and the absolute control of the flame or electrode, as the case may be. Experiments or guess work must be eliminated and welds made only according to latest approved methods. Only experienced welders should be allowed to make welds in fire boxes or any pressure work.

The time necessary for an operator to qualify as a boiler welder depends entirely upon the individual himself. Commencing, a test weld should be made at least once a week for breaking or bending test, inspection of break will show development made as well as the defects yet to be overcome. When the test pieces show operator has become proficient a test piece of standard dimensions should be submitted to the engineer of tests for final analysis and approval. If this sample test piece meets all the necessary requirements, the operator may be permitted to weld on fire box or other pressure repair work.

Welding rod material for boiler work must at all times conform to specifications for gas and electric welding rods, and none other should be used. Welding wire specifications of the American Welding Society for mild steel have been proved to give the best results.

No piece of work that is to be welded is properly prepared unless it is thoroughly cleaned and free from all scale, oil, rust, or other foreign substance. The weld must be made on clean, bright metal at all times and that condition must be maintained throughout the welding operation. Places not chipped clean in beveling or coated with oil should be cleaned with a roughing tool or sand blasted; also the metal should be cleared at least ¼" on each side of the bevel.

Carefully fit all patches, cracks or sheets allowing no more than 3/16" or less than ⅛" space at the bottom of the "V" opening. When the opening is greater than 3/16" necessarily more metal will have to be added thereby slowing up the work and allowing for greater expansion and contraction. When the opening between the plates closes to less than ⅛", welding must be stopped as the gas welding rod or electrode cannot properly penetrate to the bottom of the "V." When enlarging this opening use a hammer and chisel but when a cutting torch is used a slag or layer of oxide is left on the parts cut and unless removed, will become part of the weld, which will sooner or later show up as a defective weld.

All edges to be welded must be beveled to 45°, total 90°, except on very heavy material, one inch or over. All welders and those preparing seams for welding must be provided with a gauge for testing the bevel and opening between the plates.

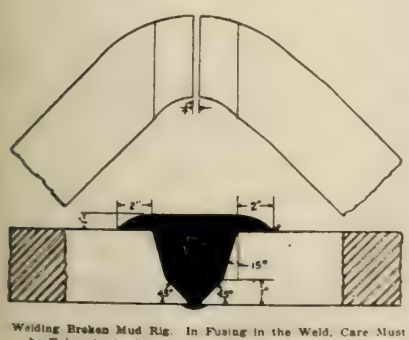
Reinforce all welds about 20% thickness of sheet which is in fire box work approximately ⅛". Where possible build up slightly from the opposite sides. Butt welding on longitudinal or cross seams, "lap" welding on flanges, sheets to be lapped ½", ⅝" maximum, ⅜" minimum.

All sheets and patches must be put on a standard or uniform line avoiding stay bolt holes where possible. Better results will be obtained where line of weld is located in center between stay bolt rows.

When cutting out sheet or patch which has previously been welded, all of the old weld must be thoroughly chipped out. It is good practice to extend patch or sheet one row of stay bolts larger or higher.

Where allowance cannot be made for expansion or contraction due to the design or shape of part to be welded, the "back step" method of welding is preferred.

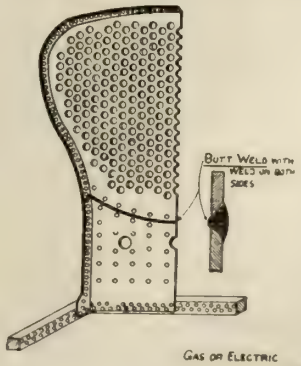
In bolting up patches or sheets preparatory to welding, it is good practice to put in a ⅝" bolt through every fifth stay bolt hole and then from the opposite side screw in staybolt between each ⅝" bolt. This will hold the sheets in line, but should the sheet warp or buckle it would only be necessary to tighten up bolt on stay bolt to again line up the sheet.



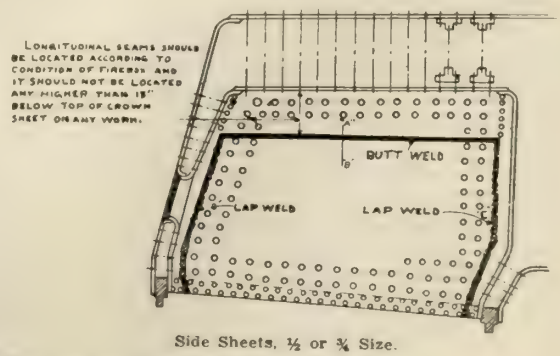
Where sheets are to be welded in fire box by the gas process it is necessary to remove the adjacent row of stay bolts as the holes will be pulled out of round and bolts cannot be tightened by hammering; however, this is not necessary when making weld using the electric process.

Certain restrictions have been placed on locomotive boiler welding known as the A. R. A. restrictions, which are as follows:

Locomotives—Autogenous Welding

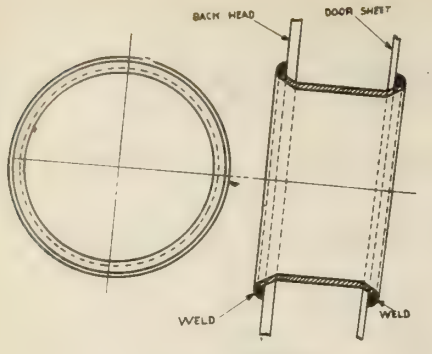


Rule No. 1. Autogenous welding will not be permitted on any part of a locomotive boiler that is wholly in tension



Paper read before the February meeting of the American Welding Society, Chicago Section.

Welding Broken Mud Rig. In Fusing in the Weld, Care Must be Taken to Avoid Fusing the Metal to the Outer Plate



Section of weld in mud ring.

Side Sheets, ½ or ¾ Size.

Welding flue and side sheets.

Welding stoker tubes.

under working conditions; this to include arch or water bar tubes. Rule No. 2. Staybolt or crown stay heads must not be built up or welded to sheet. Rule No. 3. Holes larger than 1½″ in diameter when entirely closed by autogenous welding must have the welding properly stayed. Rule No. 4. In new construction, welded seams in crown sheets will not be used where full size sheets are obtainable. This is not intended to prevent welding crown sheets to other firebox sheets. Side sheet seams shall not be less than 15″ below highest point of crown. Rule No. 5. Only operators known to be competent will be assigned to firebox welding. Rule No. 6. Where autogenous welding is done, the parts to be welded must be thoroughly cleaned and kept clean during the progress of work. Rule No. 7. When repairing fire boxes a number of small adjacent patches will not be applied, but the defective part of sheet will be cut out and repaired with one patch. Rule No. 8. The autogenous welding of defective main air reservoirs is not permitted. Rule No. 9. Welding rods must conform to the specifications issued by the Inspection and Test Section, for the various kinds of work for which they are prescribed.

Standard practice in railroad work for firebox welding includes the following: Welding of fire boxes complete; welding one-half and full side sheets; three-fourth door sheets; door collar; front and back flue sheet patches; stoker tubes; application of crown sheet; reinforcing mud-ring corners and seams; welding flue sheets; welding flexible sleeves; welding broken mud-ring; cut off and cut out stay bolts.

Welding Firebox Complete

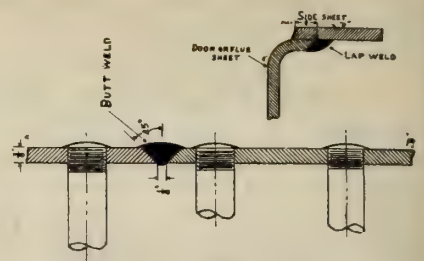
The firebox should be set up, preferably in mud-ring, with all staybolt and mud-ring holes put in, except mud-ring corner holes, which should be drilled after sheet is laid up and welded. Welding edge should be chipped to a 45° angle (total 90°) and chipped on a straight line so as to insure a uniform opening between welding edges of ⅛″. Lower portion of sheet from point 14″ from bottom of flue and door sheet should not be chipped until box is in place and mud-ring corner laid up to ring.

Bolt sheets securely in place, being sure that there is a uniform opening of ⅛″ all along welding edge. All fitting up to be done before welding is started. Hold sheets in place with strongbacks or clamps bolted through staybolt holes placed about 12″ apart. Tack sheets between clamps with a tack at least 3″ long, when clamp can be removed and welding completed.

Lap welding of flanges on door sheet, throat sheet and flue sheet (sheets lapped ½″) is recommended when sheets are fitted up in firebox, but when firebox is fitted up on the floor and can be welded from both sides, butt welding is preferred, except on crown sheet.

Welded crown sheet seam must be lower than 15″ from the highest part of crown in all cases. Where crown sheet is welded to flue sheet and door sheet, sheets must be lapped ½″ and welded on both fire and water side down at least 15″. In complete firebox installation all mud-ring rivets should be removed. Use "back step" method starting at bottom of each intermediate space, welding upwards, finishing at top of seam.

Full and Half Side Sheets



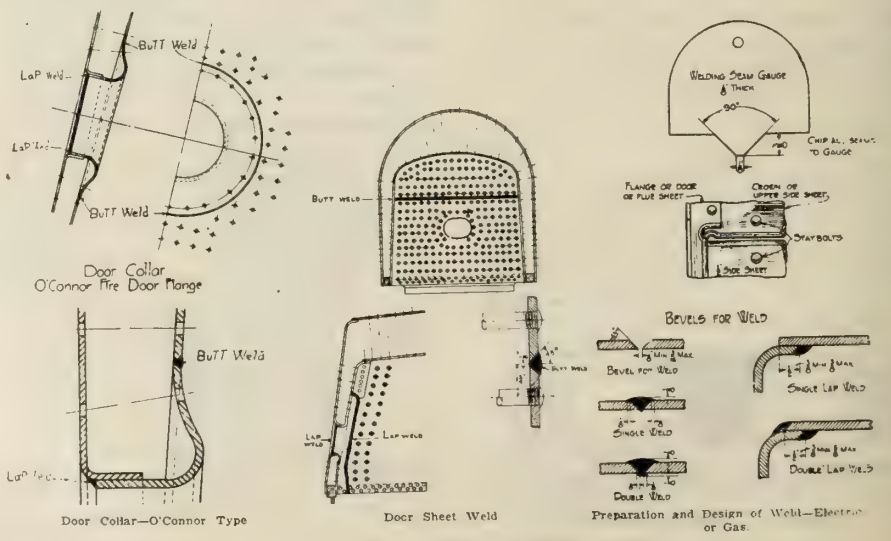
In applying side sheets, the sheet may be cut above mud-ring between mud-ring rivets and first row of staybolts, if rivets and sheet are in good condition, otherwise the sheet should extend to the bottom of the ring. The condition of the sheet will determine the location of the top weld, but this top weld must be at least 15″ below top of crown sheet.

In fitting new sheet in place standard bevel gauge with the ⅛″ opening must be used, sheet to be bolted in place to mud-ring. Staybolts may all be applied except the rows adjacent to seam which is to be welded.

Tack sheet a 3″ tack every 12″, then weld, using the back step method, alternating from center to either end. Welding on flanges must be done from the bottom up. Butt welding on cross seam and lap welding on flanges.

Three-Quarter Door Sheet

When three-quarter door sheets are applied, cut is made one, two or three staybolt rows above the door hole; condition of sheet determining location of cut. Bevel made from fire side, clamped and tacked every twelve inches, using the back step method alternating from the center of either end. Butt weld only.



Side sheet welding details.

Door Collars

Where door collars are applied, line of cut will depend on the condition of the sheet, but in all cases door collars must have at least one full row of staybolts. Avoid locating line of weld through staybolt hole. After fitting up the sheet with gauge, tack every 12″ and weld, alternating from side to side to divide the strain. Butt weld in firebox and lap weld in door hole. Lap in door hole must be laid up tight to back bead for at least 3″. Sheet in door hole not laid up properly is the cause of leaky door holes whether welded or riveted.

Flue Sheet Patches and Bridges

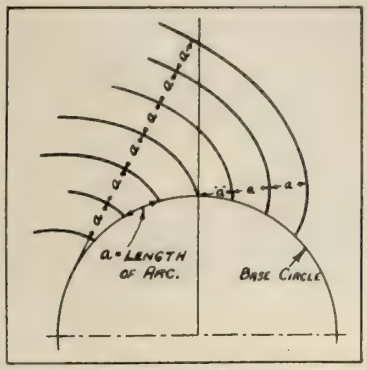
Patches on flue sheet may be welded, line of weld depending on condition of sheets. In patches through flue holes cut should he made square with bridge instead of straight across, also the cut through flange to be on a 45-degree angle instead of straight through. Patches are fitted up with all flue holes in with standard bevel and opening, clamped every 12″. Then weld center bridge first, then bridge on each side, and continue changing until welding has been completed, welding flanges. Welding to be done on fire side and in all cases reinforced on water side. Knuckle cracks in flue sheets not to be welded, when these occur apply new sheet.

Showing various methods of welding sheets.

Testing Accuracy of Gear Tooth Profiles

Generating Involute Curve—Finding Radius of Base Circle—Checking the Contour of Tooth Face—Smooth Running Features—Construction and Application of Odontometer

By H. ALTON



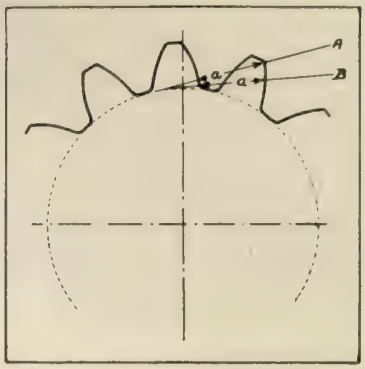
TESTING gear tooth profiles and the spacing of teeth with the same degree of accuracy obtained in many precision gauging operations is a very difficult matter. There are, of course, the well known methods of using the gear tooth calipers, and the gear testing devices which hold the gears at certain fixed centres. This latter apparatus tests the thickness of the teeth or the amount of backlash. In short, the gears are only tested as to whether or not, they will run together without interference. The precision factor really does not enter into the operation. An experienced gear inspector can detect errors in form and in spacing when using a gear testing machine, but he can tell little about their exact nature and amount.

In considering gear testing gauges and apparatus, one must not overlook the various forms of involute testing devices. These instruments are very valuable for their ability to detect and measure errors with precision Such gauges are seldom used for general shop inspection purposes. In fact they are instruments for use in laboratories largely.

The Involute Curve

Probably it would be in order to explain clearly just what an involute form of gear tooth is, as this form is the one generally used in present day practice. It lends itself to profile gauging owing to its basis characteristics. Every mechanic is familiar with the pitch circle of gears. There is, however, another circle, which must must be considered if the involute form of tooth is understood. This circle is called the base circle, and is, essentially, a circle of reference. The profile of the tooth outside the base circle is a true involute curve. The method of finding the approximate radius of the base circle graphically with an angle of pressure of 14½ degrees is shown in Fig. 1. We draw the complete pitch circle as usual. The vertical line A B passing through the centre of the pitch circle is next drawn. On the radius C D describe a semi-circle having centre of semi-circle at E. Bisect C E at F. With centre C and radius C F draw an arc which cuts the semi-circle on C D at G. Now with centre D and radius D G draw a circle. This circle is the base circle. Again referring to the involute testing devices, it is to be remembered that special discs representing either the base circle, or the pitch circle, or ratios, must be used in conjunction with them. Furthermore, the actual pressure angle employed may vary appreciably from the theoretical pressure angle specified. This is, of course, not important if the actual pressure angle is the same on all gears that mesh together. Uniformity rather than absolute accuracy as regards this factor is the more important and essential consideration. Therefore, if the base circle discs are employed, such gears may show an error in profile when tested, although they might run together properly. Thus base circle sizes would have to be determined and confirmed before the point could be definitely determined. There enters into the problem conditions that do not lend themselves to shop or production gauging. These instruments have, however, their proper places and uses.

Compiled from information obtained through courtesy of Pratt & Whitney Co.



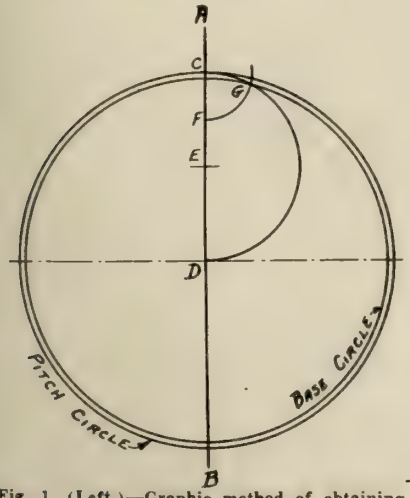


Fig. 2. (Left).—Series of true involute curves; all dimensions (a) are equal. Fig. 4. (Right).—That part of gear tooth profile between the lines A. & B. is tested by the odontometer.

Now turn to Fig. 2. Here are shown a series of true involute curves. The involute curve shown is applied to the generation of gear tooth profiles. The involute curves shown are equally spaced, or pitched, on a given base circle. The distance (a) between these involutes along a line tangent to the base circle is always the same, no matter where the tangent is drawn. This distance (a) is equal to the length of the arc of the base circle intercepted by two successive involutes.

Graphical Method

A graphical method of obtaining an involute curve is shown in Fig. 3. Take a circular piece of wood the same diameter as the base circle. Wrap around this wooden disc a thread fastened to the disc at one end and with a loop in the other end. Wind the thread completely on the disc, and then place a pencil in the loop. Unwind the thread slowly keeping it taut and the point of the pencil will describe an involute curve.

Referring again to Fig. 2, it is the distance (a) that is measured and checked by the instrument known as the odontometer. Fig. 4 shows the practical application of the distance (a). In testing any pair of profiles, if this distance does not remain constant, it indicates an error in the involute profile. In testing successive pairs of profiles, if the distance (a) does not remain uniform, it indicates an error in the spac-

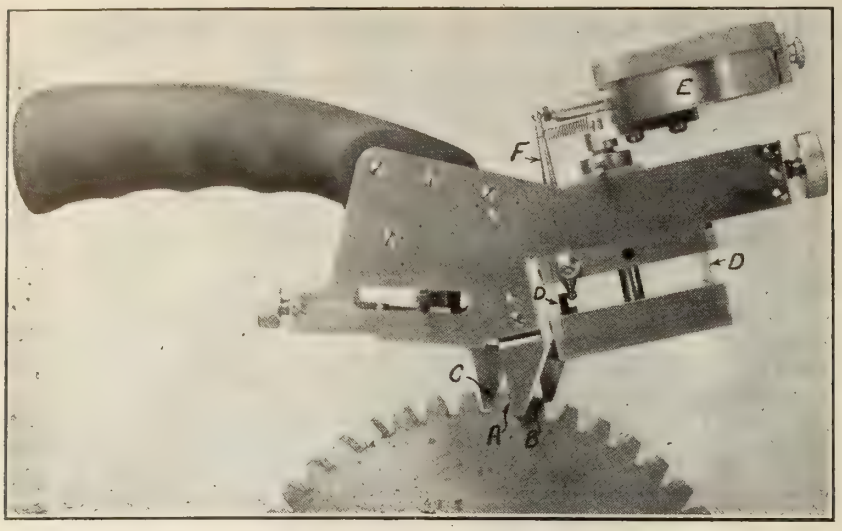

Fig. 5.—The odontometer applied to a spur gear for testing the profiles and spacing of the teeth.

ing. By referring to Fig. 4, where a few gear teeth are shown, the portion of the involute that the odontometer really tests is indicated. It will be immediately noted that this portion does not cover the entire involute flank of the tooth. These portions are known as the "overlapping" portions and are the most essential for quiet and smooth running.

Testing Tooth Profile

The odontometer is shown in Fig. 5 testing a spur gear. It is composed of a section of a straight-sided rack with two parallel effective faces, one being fixed and the other movable. A third face, set at an angle to the working faces, is used to hold the fixed working face in contact with the flank of the gear teeth. The fixed registering surface is at A, and the movable indicating surface is at B. The third surface C holds surface A in contact with the involute surface of the gear teeth. The surfaces B and C are adjustable so that the gears ranging from 3 to 10 diametrical pitch can be tested with the same instrument. No. 3 diametrical pitch means a circular pitch that is of such size that there are three teeth for every inch of pitch diameter. A gear with 10 inch pitch diameter, 3 diametrical pitch, would have 30 teeth and a circular pitch of 1.0472 inches. A 3 diametrical pitch gear, with a 7 inch pitch diameter would have 21 teeth, the circular pitch always being the same. Similarly a 10 diametrical pitch gear having a 4 inch pitch diameter would have forty teeth and the circular pitch would be .31416 inches. The indicating surface B is mounted on two thin flat springs D, which act as pivots free from back lash. The dial indicator E is actuated by the lever F which has a ratio of 5 to 1, so that each division on the dial represents a movement of 0.0002 inch of the indicating surface B.

In general the instrument is used as a comparator, to test the uniformity of interchangeable and mating gears. If actual measurements are required, the distance between the two parallel working faces of the instrument can be measured. Then, if a record is kept of the variation on each tooth, the value of this measurement between the parallel faces, multiplied by the number of teeth in the gear, corrected in accordance with the variations on the successive teeth, will give the circumference of the actual base circle of the involutes.

The instrument is made so that the dial indicator is in full view of the operator as he rocks it into the teeth. The weight of the instrument is so disposed that it rocks of its own weight into the second tooth. The handle is used only to steady the instrument and not to exert any pressure on it. The face of the fixed parallel rack tooth is made of liberal width to square up the instrument. Adjustments from one pitch to another can be quickly made. The instrument can also be used on the helical gears, the operation being identical to that on a spur gear. It is also useful in gauging and testing the uniformity of the teeth of herring bone reduction gears which are to operate at high pitch-line velocities.

The reason for the development of the instrument was the apparent need of a simple and self-contained instrument or gauge to test the accuracy or uniformity of gear tooth prifles and spacings of the teeth in production work. As stated above, it is equally adaptable to spur or helical gears, is fully self-contained, has a range of from 3 to 10 diametrical pitch, may be used to check any pressure angle, and can be applied to a gear while it is in place in the machine. A larger size of the instrument will be on the market very soon, this size being capable of testing gears up from ¾ to 4 diametrical pitch or expressed in circular pitch terms, from 4.188 inches of circular pitch to .7854 circular pitch. It is quite a simple matter to establish a definite inspection tolerance for any class of gears, as experience will soon show how much variation can safely be allowed on either the profile or the spacing before noticeably noisy gears result.

INSTRUCTION LARGELY OF INDIVIDUAL KIND

By H. A. G. WILLOUGHBY
Principal Collingwood Collegiate Institute.

COLLINGWOOD, a town of over 7,000, takes a deep interest in technical education, and the industrial and commercial committees of the Board of Education have organized various classes in accord with popular demand. For the ladies, there are very interesting classes in dressmaking, millinery and cooking, held at least two evenings a week. Commercial classes are also held two evenings a week, to give a business training, including stenography and typewriting, to those holding clerical positions, and desirous of improving their standing. During the present term, a large class enrolled for basketry and wood-work, and this class has proved very popular as a night course.

Up to the present it has been found advantageous to carry on a class in mechanical drawing. The object of such a class should be mainly to give the students a knowledge of working drawings, to enable them to read blueprints correctly and also the ability to make simple drawings, and freehand sketches. It is not the intention to produce finished draughtsmen, but a small amount of geometrical construction has been found helpful to those who are apprentices in a machine or wood-working shop.

A general outline of the course followed in the Collingwood evening classes is given below:—Mechanical Drawing—purpose, how it differs from other drawings.

Views shown in a mechanical drawing, relation of these views.

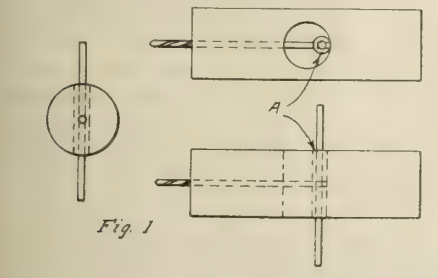
Drawings showing two views of simple objects, dimensioning and lettering, drawing to scale, conventional lines used in mechanical drawing, drawings to illustrate the application of all of these in the making of a working drawing.

Sectional drawings, assembly and detail drawings, inking in of drawings, freehand sketches of objects with all necessary explanatory measurements, these sketches to be used by the student in producing a working drawing without further reference to the object itself, and isometric and cabinet drawings.

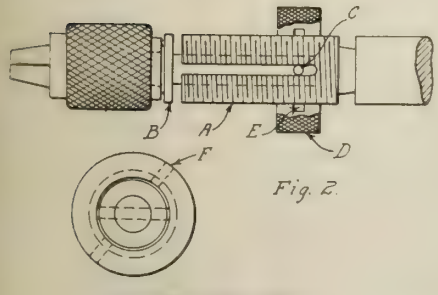
On Dec. 1, 1919, the industrial committee opened day classes in navigation and marine engineering. The purpose of the nautical class is to provide the academic training necessary for the various grades of officers for the Canadian Merchant Marine. The subjects taught are as follows:—Preliminary—elementary arithmetic, including logarithms, decimals, square and cube root.

Navigation—problems to determine the shortest distance between any two given points of the earth's surface. How to find the position of a vessel after measuring the angular height of a

(Continued on page 44)



Practical Ideas for Shop Executives



SENSITIVE DRILL HOLDERS

By Harry Moore

The use of small diameter drills on machines designed for such purposes may be quite safe and productive of good work, but attempts to use these delicate tools on heavy machines quite out of proportion to the size of hole required, usually results in a heavy mortality of drills. It is sometimes necessary, however, to do this, and when the amount of work justifies it, some kind of sensitive holder will amply repay the time taken to make it.

Turret lathes with their provision for powerful leverage are examples of suitable machines for this kind of work and in Fig. 1 is shown a simple type of holder that was used for drilling a short hole in brass bars on this kind of machine. The holder is just a piece of cold rolled drilled by the drill to be held in it, and a suitable size hole drilled at right angles through it. A piece of rod A is tapped right through and drilled in the center and this together with two short pieces of wire threaded into it forms the means of holding the drill from rotating, and also leverage to feed the drill into the work. The whole thing is held in a suitable holder in the turret which is set so that the drill point touches the work when the machine stop is reached. The work, travelling at high speed is easily and safely drilled

Sensitive Drill Holders.

then, by hand pressure on the two handles.

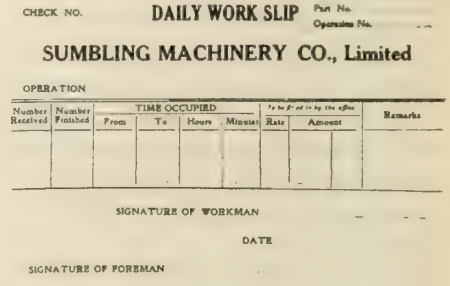
An engine lathe tailstock is another device that admits of leverage easily applied, but yet which gives the operator very little "feel" on delicate work. Fig. 2 shows a more elaborate holder, but one many times more useful as it holds a small drill chuck. The shank of this holder fits the tailstock spindle, and is threaded for the full distance of the straight outside diameter A. A hole drilled in the center takes the piece B which in turn takes the drill chuck. In the shank of B a pin C is driven that works on the slot in A. Knurled nut D threaded to fit A has a recess E cut in the center to clear the pin C, and also a hole F clear through to enable the pin C to be inserted in place when the holder is assembled. This is a very sensitive holder with which the operator can at all times "feel" the proper amount of pressure required, and which allows for rapidly backing the drill out of the hole by a twirl of the nut D.

GAUGING CYLINDRICAL HOLES

A very useful hint with regard to the above subject is as follows: To estimate the size of a cylindrical hole by the "play" or "travel" of a gauge, take the length of the travel of the point gauge in 1/16". Square this and divide by twice the size of the gauge in inches. the result gives the number of thousandths of an inch the hole is above gauge size. Suppose a 3" point gauge has 3/8" play; the play will be six sixteenths; $6^2=36$, hence $36\div6=6$, and the hole is 3.006" in diameter.

KEEP FLAME CLEAN

A smokeless flame is very essential if an article is to be successfully brazed. A brazing lamp using petroleum, a gas blow-pipe, or a blacksmith's hearth may be used for the purpose of heating the article to be brazed. The article should be laid on a heap of broken coke, which should be heaped around the work in the immediate vicinity of the prepared joint. Before commencing the work the spelter is mixed with crushed borax and water and carefully placed in position; the heat is then applied gradually until the water is evaporated; it is then directed onto the spelter until it fuses. Great care should be taken to see that the article is perfectly clean before commencing to work on it.



LUBRICATION OF MACHINE TOOLS

The lubrication of machine tools is largely done by hand. Experience has shown that bearings lubricated in this way are often neglected. It is essential that careful attention be given to a regular routine of oiling the tools, in order to prolong their life and minimise the frictional losses, which, in the case of light and medium high-speed machine tools, may amount to as much as 50 per cent. of the full shop load. Care should be taken to see that all oil holes are protected from entrance of dust by covers. It is the practice in some cases to place felt pads in the oil passages leading into the bearings, in order to receive the oil during each oiling, and afterwards gradually allow the oil to pass into the bearing surfaces, so that the lubrication becomes more regular, and therefore more efficient, than would be the case if the oil was fed direct to the bearing by hand oiling without the felt pads.

A SIMPLE TIME CARD

By J. H. M.

Several types of daily work reports are used in machine shops and manufacturing plants, but the one shown in connection with this article has proved very satisfactory to the firm adopting the same. Several colors are used for different work, white being for staple work, yellow for tools and equipment, blue for jobbing, and pink for expense. By expense is meant time spent for which there is no return, such as interviewing visitors to the plant, etc. This simple form keeps a close tab on the different jobs passing through the factory.

SOME SPECIAL TAP WRENCHES

By Harry Moore

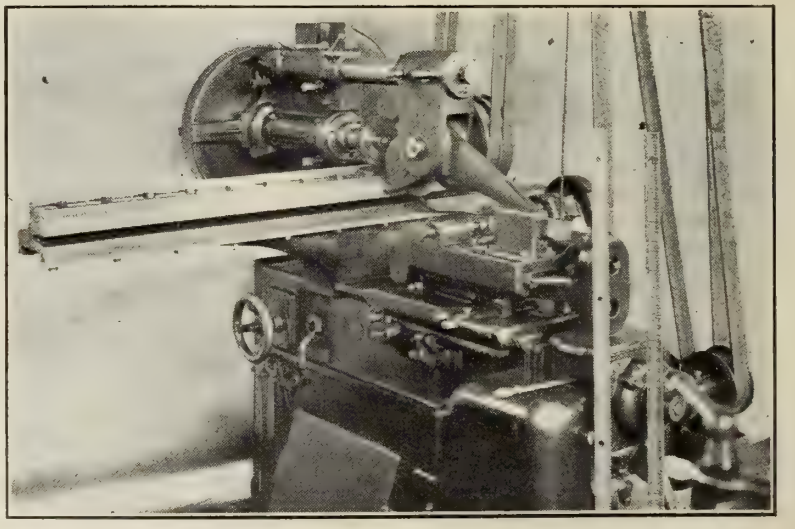
The regular adjustable tap wrenches which form part of the equipment of all shops leaves very little to be desired in the ordinary run of work, but there are occasions, as every mechanic knows, when they do not quite fill the bill. Sometimes it may be that production would be speeded up by a wrench designed specially for the job, while at other times the nature of the work compels such a design. In the former case the number of pieces to be tapped would be a determining factor, and in the latter there would be no alternative. There are any number of other instances where conditions call for something different to the standard wrenches.

Some special tap wrenches.

Some of these conditions and the wrenches devised to meet them will perhaps be of interest to those who have or may be at some time or other, faced by similar conditions. The wrench shown in Fig. 1 is a time saver when used for bottoming threads where all three taps, taper, second and plug, are used in the operation. The actual holder is made from two pieces of round stock A and B having 3 Vees cut in their faces equi-distant apart, while between the vees are three tapped holes for tightening screws. One piece B is driven tight on the center of handle C, the other is a sliding fit. The method of holding the taps is clearly shown, the advantage being of course that no time is lost changing from one tap to the other. As one is used, the wrench is simply turned round to bring the next in position, both idle taps being well out of the way all the time.

The extension wrench shown in Fig. 2 has a rather unusual feature inasmuch as it holds the tap in the wrench. This was found necessary in tapping a number of holes in such a position that it was quite an operation to recover a tap if it was dropped. As some kind of wrench was needed to reach into the work and hold the tap as well, the one shown answered the purpose very well, all things considered. The shank of this wrench A is drilled at the end to take the shank of the tap and through the side a hole of similar size is drilled to take the tightening piece B which is a stud sawn off and case hardened when finished. A slot is cut in the center of B to a depth of about half the diameter and a width equal to the width of tap square and near the plain end a small hole is drilled so that a piece of wire can be inserted to prevent the piece turning when the nut is tightened. When in use the tap is pushed up the hole in the end of A and the nut tightened, thus binding the slot securely against the square of the tap. The usual piece of rod is used on the upper end of wrench as a handle. It is interesting to note in connection with this wrench how an apparently fairly complicated tool can be cheaply made. A little study will show that although this wrench looks more elaborate than a socket wrench, the latter requires a broached hole; an expensive item where only one is required; whereas the former is just a straight drilling job, apart from the slot which can be filed in a few minutes.

Another difficulty frequently encountered is the tapping of holes in positions where space is restricted, and therefore the wrench has not a free movement, but must be given very short turns, or mere "twitches" at a time. The wrench shown at Fig. 3 was devised to meet conditions similar to this. Had there been enough clearance in this instance, to allow a wrench to be lifted off the tap square and replaced in a convenient position there would perhaps have been little gained in the making of it, but such not being the case it was well worth while, as it answered the purpose as good as a ratchet wrench which was not at hand at the time. A steel disk A was drilled with a circle of holes, drilled in the center and filed out square, then driven tight on the tap square. The wrench B which was just a piece of rectangular stock had a hole drilled in the center large enough to clear the corners of the tap square, and a pin driven in tight to engage the holes in A. After tapping a few holes, the action of lifting the wrench up a little after each turn, to clear the pin, became almost automatic and entailed little delay.



KEEP CUTTING EDGE KEEN

One frequent cause of poor milling results is allowing the edges to become dull, rather than go to the trouble of re-grinding. If they are allowed to become so dull that their bluntness can be seen with the naked eye, the cutter will fail to work at its proper speed owing to overheating, caused by some edges becoming more worn than others.

RACK CUTTING ATTACHMENT

By R. Harrison

The accompanying illustration shows a simple and highly efficient rack cutting attachment, designed to fit a B & S. gear cutting machine. The work being operated on is the mild steel trip rack used on the reversing mechanism of a grinding machine. The attachment has been in use a number of years, during which time it has given consistently good service, the only renewals being the replacement of worn milling cutters. It will be noted that full advantage is taken of the automatic movements of the machine to obtain accurate indexing and the positive intermittent action of the cutter head. Three teeth are cut at each cycle and production is at a rapid rate, the cut being taken at each reversal of what is normally the cutter slide. It will be seen that this slide carries a simple form of cam which depresses the lever operating the auxiliary cutter head as it advances. Continuous motion is imparted to the cutters through the double belting and large diameter pulley shown on the right of the fixture.

Rack Cutting Attachment on B. & S. Gear Cutter

New Things in Shop Equipment

CUTTER AND GRINDER ATTACHMENT

A new tool for the grinding of Curvex Milling cutters has been placed on the market. When it is desired to grind a Curvex cutter, the piece is mounted on an arbor between the centres of the attachment. The table is set at the zero point. From a chart of leads and angles, the taper guide bar of the attachment is set at the required angle. The table is fed horizontally, thus the cutter spindle is automatically revolved in the proper relation to the lead and spiral angle. The cutter is indexed by a plunger and index plate. The wheel spindle is mounted on an angular raising block to bring the wheel spindle to an angle of 15 degrees from the horizontal.

A special grinding wheel is used, the front face of which is dressed vertically to insure a single line of contact between the wheel and the work. This enables the work to be fed vertically to the wheel. The knee is swivelled to an angle corresponding to the helix angle of the cutter, and the table is moved past the wheel by a rack and pinion. The grinding plane is always on a true radial line from the centre of the cutter and the wheel always clears itself from the work. The wheel is dressed on the face by clamping a diamond on the table and using a vertical feed. The R. K. Le Blond Machine Tool Co., Cincinnati, Ohio are the makers of these tools.

VERTICAL DIE SLOTTING MACHINE

A rather unique vertical die slotting machine, having several interesting features has recently made its appearance. It is especially adapted for machining round, square, and irregular-shaped punches and dies. The ram is driven by a connecting rod and disc crank mechanism. The disc crank is connected to the main shaft of the machine, which shaft is located at the top of the tool. The crank pin is adjustable so that any length of stroke up to four inches may be obtained. The member on which the ram slides, and to which it is gibbed, is hinged at the top in such a manner that it can be set at a slight angle relative to the face of the column, in order to produce a clearance in die openings. The crank arm, or connecting rod, at the lower end is connected to a pin which is located in a slot in the ram.. This allows an adjustment of the ram relative to the crank arm. The lower end of the member on which the ram slides, may be connected to a toggle mechanism operated by an eccentric on the main shaft. When connected, the mechanism moves the ram over a curved path on its down stroke, thus permitting of certain curved cuts to be taken in dies. The mechanism also causes the tools to clear the work on the upward return stroke. Cross, longitudinal, and circular hand feeds of the work are each obtained through separate screws. Power feeds can be furnished if required. A variable speed gear box mounted inside the column furnishes three changes of speed. The machine is belt driven and is furnished with fast and loose pulleys. The machine is manufactured by the Peters-Bossert Co. of Cincinnati, Ohio.

SENSITIVE DRILLING MACHINE

A 12-inch sensitive drilling machine driven by a built-in electric motor with friction drive, has recently been developed. The motor is located on the top of the column and is mounted on a horizontal shaft, on the end of which is located a small friction disc. A larger friction disc is located on the vertical spindle of the machine. The motor and friction disc are mounted on ball bearings. The frictional pressure of the drive is governed by the weight of the spindle disc, thus being constant and requiring no adjustment. The friction drive is completely enclosed and is so constructed that the friction surfaces are kept free from oil. A spring counterbalances the spindle. The range of spindle speed can be easily adjusted from 450 to 1,200 r.p.m. A weight in the column counterbalances the table. Motors can be furnished to suit all standard circuits. The starting switch is also built into the machine. The tool is made in both bench and floor designs. V-blocks, cup and point centres are also provided. Some of the principle dimensions are as follows:

Greatest distance from table to nose of spindle 39 inches. Vertical adjustment of table 32 inches. Vertical adjustment of spindle arm 8 inches. Maximum height with spindle raised (Floor Machine) 76 inches. Diameter of spindle in sleeve 13/16 inches. Diameter of table 11½ inches. The spindle socket has a No. 3 Morse Taper. The motor is ½ horse power and has a speed of 1,725 r.p.m. The machine is manufactured by the Louisville Electric Mfg. Co., Louisville, Ky.

FACING AND BORING MACHINE

A machine that faces both sides of an automobile wheel to the proper thickness and bores the hole at one setting has been recently marketed. This insures that both sides will be parallel, and at the same time is a time saver. The wheel is chucked in the horizontal plane and one cutter head is above the work, while the other is below it, in the base of the machine. After chucking, the operator actuates a lever that brings up the lower head, which faces the underside of the wheel. As the spindle of this head moves upward it brings a gauge with it, which the operator locks on the completion of the operation. The upper spindle is then brought down. This spindle bores the hole and faces the top of the hub simultaneously. As the upper spindle comes down, a rod controlled by it strikes the gauge referred to above, when the hub has been faced down to the right thickness and prevents further downward movement of the spindle. The spindles are then returned to their original positions, the gauge released, the wheel removed, and another wheel put in place and the operation repeated. The lubrication system provides forced oiling to the pulley drive bearings and also to both spindle quills. The pump, which is an integral part of the machine, can be arranged to deliver varying quantities of oil. Ball bearings are provided throughout. The drive is through a countershaft located on the back of the machine near the floor. The power is transmitted from the countershaft to the spindle quills by 3 inch single ply belts. The Blomquist-Eck Machine Co., of Cleveland, Ohio, are the manufacturers.

NEW GAP SHEAR

A very rigid and especially useful type of gap shear has recently been developed. The new shear has a gap in the housings which facilitates the splitting of long plates. The machine is built in several sizes. The six foot machine can handle annealled steel up to ⅜-in. thickness. The cutter-bar or cross-head is of double and cross ribbed box construction, and is provided with long bearings, fitted into the slides of the housings by means of adjustable hand scraped taper gibs. This construction prevents springing and deflecting under strains. The long bearings prevent the cross-head from tilting and consequently it cuts clean. The cutter-bar is connected by the eccentrics by means of adjustable links. With this construction the shear knives may be set, by raising or lowering the cutter-bar, either to split long stock or to do plain shearing to the full length of the knives.

The eccentrics are double keyed and shrunk on the eccentric shaft. The eccentric shaft bearings are split and adjustable, and can be easily renewed or replaced. All shafts are of large diameter, and the gears are machine cut. The large gears are semi-steel castings and the pinions are steel forgings. The clutch is made of forged steel and is fit-

ted with a tool steel clutch pin and finger. The hold-down, or clamp, is automatically operated and is equipped with compensating springs to take care of unevenness or variation in the thickness of the metal to be sheared. The bed of the machine can be adjusted to suit the requirements of the work.

A full set of front, side, and back gauges are furnished. The back gauge is operated through a crank handle, shafts and mitre gears. Parallel graduations in sixteenths of an inch are marked from the edge of the shear blades to the ends of the front gauge supports, to enable the operator to set the gauges quickly and accurately. This shear can also be arranged with a motor drive and equipped with a long squaring arm. Some of the specifications of the six foot size are as follows:— Length of shear blades 74-inches; size of flywheel pulley 42-inches by 7-inches; Speed of flywheel pulley 280 r.p.m.; strokes of cutter bar, 18 per minute; and the ratio of the gearing is 16 to 1. The machine is manufactured by the Streine Tool & Mfg., Co. of New Bremen, Ohio.

AUTOMATIC ROTARY SURFACE GRINDER

A new automatic rotary surface grinder was recently exhibited at the New York Automobile Show. It was designed especially for the grinding of piston rings and also the sides of ball and roller bearing races, collars, washers, gears and other similar work. The machine is designed for large production. All the units are well guarded. The machine complete weighs two tons. The wheel slide operates on "V" ways and is controlled through a hydraulic arrangement, operated by oil which enables the operator to instantly get any speed from zero to maximum. This drive also makes it possible to reverse the table instantly at any desired point without shock or noise. The chrome vanadium steel spindle is mounted in a straight plain adjustable bearing at the wheel end, 2⅞ inches diameter by 6¾ inches long. The rear of the spindle is carried in a self aligning ball bearing. The main drive shaft is mounted on roller bearings. It has a two step cone, giving two wheel speeds, which enable the wheel to be operated at an efficient speed throughout its life. The chuck spindle is mounted on ball bearings and is driven by spiral gears.

When the machine is used for general work without the automatic feeding device, the chuck bracket can be adjusted to allow for grinding concave and convex surfaces. An automatic feeding arrangement is furnished with the machine when it is to be used for handling rings, ball races, collars, washers, etc. With this arrangement it is only necessary to load the magazine and take away the finished product, all operation being entirely automatic. A diamond for dressing the wheel and governing the finished dimensions of the work is an integral part of the machine. The chucks employed are of the magnetic type and provision is made for demagnetising the work at each indexing point. The mechanism cuts off the current and for an instant reverses it. This procedure not only demagnetises the work but allows the automatic feed to operate more easily.

A cutting lubricant pump is not supplied as standard equipment, but can be easily applied. An automatic vertical feed can also be furnished as an extra on all style machines. when used for general work. It is not adaptable to a machine furnished with a ring feeding device. The machine can be furnished with either the 8, 12, or 16 inch Heald Magnetic Chuck, according to the size required. The automatic feeding device can only be furnished on the 8 inch style. A 10 to 15 h.p. motor is recommended to drive the machine according to the nature of the work. The machine is manufactured by the Heald Machine Co., of Worcester, Mass.

PIPE THREADING MACHINE

A large pipe threading and cutting machine, capable of handling pipe from 4 in. to 12 in. in diameter has been recently developed. The range of the machine may be further extended down to pipe of 2½ in. diameter by the addition of some special features. Two die-heads of the stationary type are employed, one to thread pipes up to six inches and the other to thread the pipes over six inches and up to the capacity of the machine. The entire range of each of these die heads is covered by one set of chasers. The pipe chucks have three jaws, which are geared and have universal adjustment. They are also self-centering. The rear chuck has grips to provide for fitting up flanges. The carriage carries the die-heads, the cutting-off tool, and the reaming tool. The carriage may be moved by power or by hand, and has a single control lever. Automatic stops prevent the carriage from coming in contact with the chuck at one end and from running off the guides at the other end. The setting of the reaming tool is accomplished quickly, and the tool is advanced to the work by the operation of a hand wheel.

The machine has a single pulley drive, but eight speeds are obtained through the medium of a change gear box. The power is transmitted to the machine from the constant speed pulley shaft through a friction clutch, which is operated by either of two levers, conveniently placed at either end of the working side of the machine. This enables the operator to control the machine when fitting up flanges at one end. Motor drive is accomplished by bolting a motor to the back of the frame of the machine and using a silent chain drive, substituting a sprocket for the constant speed drive pulley. The machine weighs 13,000 pounds and is manufactured by the Landis Machine Co., of Waynesboro, Pa.

CENTRE DRIVE LATHE

A rather unique design of lathe has recently been placed on the market. The head stock of the lathe is in the centre of the bed. The lathe is electrically driven by a motor bolted to the back of the bed. Power is transmitted to the live spindle in the head stock by means of silent chains and sprocket wheels. The live spindle is made of cast iron and has a large central hole through it. The head stock is equipped with two chucks one at each end of the spindle which are generally of the floating type. These chucks position themselves relative to the outside diameter of the work when the jaws are tightened, at which time the chucks are securely clamped against shoulders on the spindle. By means of this construction the work is held rigidly, is positively driven, and maintains its natural position without deflection. In cases where the work is very short one chuck is omitted to permit the carriages to come closer to the head stock.

The spindle rotates in cast iron journals. The motor is at least 7½ horse power. The driving mechanism is controlled by a foot treadle at the front of the machine. This pedal functions through a clutch, starting and stopping the machine with the motor running continuously. The left hand tail stock has an extra large spindle with two holes running through its entire length, one of these holes being for the purpose of carrying a standard centre while the other is a clearance hole through which the work is telescoped when loading and unloading the machine. By withdrawing the index plunger at the front of this tailstock its spindle may be revolved and either of the two holes indexed in alignment with the spindle of the machine. There is no endwise adjustment of the spindle in the left tailstock. The right hand tailstock spindle has longitudinal motion similar to that of a standard lathe tail stock. Either tail stock may be clamped and moved along the bed to suit long or short work. The carriages have automatic and individual feed trips, and when tools are being automatically returned to their starting positions, they are withdrawn slightly from the work so as not to score it. Both carriages, when the tools are cutting, travel towards the head stock. A back-arm attachment to both carriages has been supplied on several of these machines, so that squaring of shoulders, as well as the grooving of shaft ends can be performed simultaneously with the turning operations.

The original idea was developed some four years ago when a machine of similar design was built to machine Ford automobile driving shafts. The new machine incorporates several new features. On a machine designed for turning shafts up to 2⅞ inches in diameter and having a 9-foot bed, the maximum distance between centres is 72 inches. The machine is manufactured by the Reed-Prentice Co. of Worcester, Mass.

Is New Regulation Being Broken?

ON FEB. 1st an amendment to the customs law was put into effect, which did away with the requirement for goods to be invoiced at "a fair market value for home consumption," or words to that effect. It was found that in many instances, goods in foreign countries in general, and in the United States in particular, were being sold at prices that were without doubt below the cost of production. This was done for various reasons, to increase the volume of work in factories in order to reduce the cost of production per unit, to dispose of a side line, to raise cash quickly, etc.

A large volume of these goods are said to have found their way into Canada, and, of course were invoiced at the prevailing prices in the home market. The new regulation has been framed to circumvent this condition and it requires all goods imported into Canada to be invoiced at a figure that represents "cost of production plus a fair margin of profit to the manufacturer or producer." It is understood that a number of shipments have been imported into Canada by the Canadian Metal Working Industries, and that these shipments have been purchased and invoiced at a price that would not qualify under the new regulations. In many instances the goods have been sold, "delivered," the consigners paying the duty. Many of these cases are being investigated at present, and there is every probability that corrected invoices will be demanded and the goods re-entered. The cases where the goods were purchased "delivered," is interesting, as the vendors will no doubt be forced to bear any additional expense in this connection.

It is not a patriotic spirit that prompts a firm to take advantage of such unusual conditions. It is bound to react on the whole country as this form of unfair competition is present in practically all lines of semi-manufactured and complete manufactured goods. It is, in the end, bound to increase unemployment and is detrimental to the country in a multitude of ways. It is a form of "dumping." The good it does to a favored few is largely imaginary. All manufacturers and importers should take this matter up at once and insist that Canadian workmen in Canadian factories are permitted to supply Canadian requirements. At this particular time when business is so depressed, and unemployment so general, it is most important that such practices be checked.

What Will Be Its Future?

OCCASIONALLY some engineer comes along and disturbs the peace of mind of the engineering profession by discovering something entirely out of the conventional rut. This is a good thing as it prevents stagnation of ideas and dry rot. The average designer, if asked to describe a gear tooth would proceed to discuss the forms in general use, and if well versed in the science, might go back so far as Appolonius of Perga, who is claimed to have been the first one to derive the conic sections from a single cone. From there he might proceed to tell how the first gear was composed of flat pieces of wood arranged in the form of a cross, and would perhaps enlarge on the various types of teeth now in vogue, discussing tooth pressures, clearances, etc., but it is very doubtful if he would touch upon the form of gearing shown on another page of this issue, for here we have something entirely new to the engineering profession, and known as the autopitch gear.

In this new design the inventor has attacked the pinion as the offending member, and in place of the regular accepted theory, has made the pinion almost one continuous tooth composed of hardened rollers. Adaptability is covered in the inventors' claims, also elasticity and noiselessness. So far as efficiency and economy of power are concerned he is not able to give any definite figures, but claims that recent running tests have proved entirely successful.

Several questions arise in our mind regarding the feasibility of this new departure. Will the rollers offer sufficient resistence to drive the gear? Will they soon become worn to such an extent that slip will occur, or will the rollers become distorted in use on heavy drives? These are only a few of many thoughts which arise when contemplating this new type of gearing, and it is very unlikely that the new departure will revolutionize existing methods. However, it starts a new thought, which, with further development and research work, may be of decided value to the engineering profession.

Why Should This Condition Exist?

WHEN THREE firms from one city decide inside of a few months of each other to close shop and move to another city, it is high time to ascertain the cause. Upon investigation we find that the root of the trouble lies with labor and its demands. Although these firms only employ about twenty hands each, the principle is the same, viz., that they have found a locality where they can secure contented help at a reasonable figure. Like many other concerns, these three establishments found their operating costs too high for the new levels of selling and after an attempt to show their employees the need of wage reductions they were forced to move as their workers refused to accept any cut.

What happens to the men who refused a lower scale of wages? Have they secured positions at an equal rate? We have had no opportunity of following this up, but it is a safe conclusion that a large percentage are still looking for a job. Thus, the stubborn attitude acted as a boomerang. Labor, as well as manufacturers, must consider existing conditions when asked to accept temporary reductions, otherwsie a return to a true level of business will be delayed.

A seaplane can fly from Halifax to Vancouver and descend on a lake or a river within easy reach of supplies, at intervals not exceeding 150 miles.

Keen Competition Exists In Tools and Supplies

Pig Iron, Non-Ferrous Metals and Scrap are All Dull—Steel Orders Increasing Slightly and Prices Stiffen—Wood Working Tools in Better Demand

ALL MARKETS MERELY HOLDING THEIR OWN

A REDUCTION of approximately 10 per cent., in one line of Canadian-made machine tools has taken place during the week. New lists are in the hands of the dealers, and it is expected that this move will stimulate business, otherwise Canadian markets remain the same.

Pig iron is dull, and until foundries secure more orders this condition cannot improve. Scrap metals continue weak at the decline recently recorded, and little business is being closed. As this market is largely dependent upon foundries for its business, no improvement is looked for in the near future.

Sheets, plates, small shapes and boiler tubes are moving best of all in the iron and steel trade. Prices are firm, but have not yet advanced in proportion to the increase in the States. Should the advanced prices on the other side hold for any length of time, quotations would probably rise here in like proportion.

Machine tools are fairly active but no improvement over last week can be reported. Several prospects look encouraging, but this supposition does not show up to advantage on the books.

Small tools and supplies are merely holding their own. It is doubtful if March will show any improvement over February. This month started off with a rush but has tapered down, probably owing to the keen competition existing. Prices remain the same on the lists, but it is a known fact that these are quite often shaded in order to land a good sized order. As high as 20 per cent. reduction is spoken of in some quarters, so keen are dealers for business. Most of these reductions occur on drills, other lines being more stable.

Wood working tools are slightly improved, although the spring demand has not come up to expectations. Oils and greases, waste, and steel pipe, all show a slight increase in demand, but several reductions in the price of oil have taken place during the week.

In the United States the rate of steel production remains the same, 55 p. c. A higher rate is not expected, the belief existing that the present rate is rather high for existing conditions. The production of steel for domestic consumption is at the same rate as in 1912 and 1913, the two best years before the war.

Interest centers around the possible coal strike on April 1st, and from present outlook, the miners will drop their tools on that date. The new rates offered to the men involve a reduction of 30 per cent. Coal is quite soft, selling as low as $1.80 for steam mine run, when $2.10 has been the minimum for many months. This softening is caused through consumers having already stocked up. The steel mills are not worrying over the possible strike as they have good stocks on hand.

There is a possible chance that orders for steel may drop off a little, as many are said to have been ordering material before the miners went out. Thus, stocks are heavier than they were. Prices in steel products are stiffening a little, 1.40c for bars, shapes and plates being the lowest figure now quoted. Others call for 1.50c. Sheets remain firm the prices being 3..00c for black, and 4.00c for galvanized.

Basic pig iron has advanced 25 cents, being once more $18, valley. This is the third time during the last nine months that it has reached this mark.

Toronto

March 22.

THERE IS practically no change on the local market so far as volume of business is concerned. Any improvement which may have occurred was looked for, because as season advances, certain lines pick up. One machine tool manufacturer announced a reduction of approximtely 10 per cent. on his line of tools this week, hoping to secure additional trade by this move.

Pig Iron.—The demand for pig iron is almost non-existent. Foundries remain very dull, and until they get orders from the manufacturer, there is little likelihood of the pig iron industry picking up. The existing quotation is $27.15.

Iron and Steel.—A fair volume of orders is reported in this market, sheets, plates, small shapes and boiler tubes being best of all. So far no step up in prices has been made to line up with the advance in the States, but existing quotations are stronger than formerly. Should the recent stiffening hold on the other side of the line, it is quite possible prices locally will go up in like proportion. Orders for iron and steel are coming in from a scattered territory, the variety of customers being increased every week. This is a healthy condition. Following are present quotations:

Iron bars	2 75
Steel bars	2 75
Reinforcing bars	2 75
Steel hoops	3 75
Tire steel	3 00
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in. base	3 25
Small shapes	3 00

Non-Ferrous Metals. — This market shows little change. Prices remain the same, and the demand is light. Copper producers are contemplating resumption of operations, this being suggested as a cause of the hesitancy of consumers from coming into the market. Production will likely be around 40 per cent., and some believe that lower prices will result. Predictions made by those in authority say that this theory will soon be exploded, when belated buyers will enter the market at perhaps higher prices than now exist. Following are present quotations:

Lake Copper	17 00
Electric Copper	16 75
Castings, copper	16 50
Tin	34 00
Spelter	7 25
Lead	6 75
Antimony	8 00
Aluminum	27 00

Machine Tools.—As stated in opening paragraph, one maker has announced lower prices. Business in this line remains much the same. It is largely a question of how the morning mail shapes up. For example, one large establishment we visited had received a wonderful mail, and were highly optimistic, while another had received nothing but dead wood, and felt the bottom had dropped out of the market. None of these opinions are correct, but viewing present conditions with the start of the year, things are somewhat improved. However, if placed alongside of last week, there is no change.

Wood working tools are fairly active, but spring expectations have not been lived up to. Further improvement is expected in the near future.

Scrap Metals.—If anything, the scrap market has stiffened, but the movement is so slight as to be hardly worth considering. Red and yellow scrap is a little more active, but buying has not been on a large enough scale to advance prices. White metals are steady in price, but very slow in movement. Cast iron continues the same as last week, but steel grades are very dull. Following are quotations:

Copper, light per 100 lbs.	8 00
Copper, crucible	10 50
Copper, heavy	10 50
Copper wire	10 50
No. 1 composition	8 50
New brass cuttings	6 00
Red brass turnings	6 00
Yellow brass turnings	4 75
Light brass	3 50
Medium brass	4 50
Scrap zinc	3 25
Heavy lead	4 00
Tea lead	3 00
Aluminum	10 00
Boiler plate, per gross ton	9 00
Heavy melting steel	9 00
Axles (wrought iron)	17 00
Rails (scrap)	10 00
Malleable	10 00
No. 1 machine cast iron	18 00
Pipe, wrought	7 00
Car wheel	18 00
Steel axes	16 00
Mach. shop turnings	4 00
Stove plate	16 00
Cast boring	3 00

Small Tools and Supplies.—When March is considered alongside of February, it is doubtful if any improvement will show in these lines. The month started off well but gradually tapered down, possibly owing to the keen competition existing, this in turn holding the buyer out of the market until he saw which way the cat was going to jump. It is a well known fact that standard quotations are being shaded considerably where the order is particularly desirable, and some claim that as high as 20 per cent. has been lopped off to secure a good sized order. This shows how keen competition really is, but when such chopping of figures occurs, it is usually drills that are being quoted as other lines are more stable.

Miscellaneous.—Oils, greases, waste, and steel pipe are all holding their own. A few reductions in the price of oil have taken place, and following are existing prices on these lines:

OILS AND COMPOUNDS

Castor oil, per lb.	34½
Royalite, per gal., bulk	21
Palacine	24
Machine oil, per gal.	33 00
Black oil, per gal.	17 50
Cylinder oil, Capital	61 50
Petroleum fuel oil bbls., net	9 90
Pure turp., single bls. gal.	1 35
Linseed oil, raw, single bls.	1 00

WASTE

XXX Extra	16	Atlas	18
Peerless	21	X Empire	13
XX Grand	15	Ideal	18

X L C R	14	Fancy	13½

Colored

Lion	12		
Standard	10½	Popular	9
No. 1	13	Keen	7½

Wool Packing

Arrow	30	Anvil	20
Axle	25		

Washed Wipers

Select White	18	Dark colored	13
Mixed colored	14		

Montreal

March 22.

IN MANY lines business continues to improve as the season advances. The scenes along the harbor front are more or less representative of what is occurring in many lines of the iron and steel business. Over five hundred men were taken on by the Harbor Commissioners during the past week. The new cold storage plant is rapidly nearing completion, and is expected to be ready at the opening of navigation. This plant is stated to be the third largest in America, as there is a large amount of high class machinery in the building, it will prove the means of employment for a large number of men as soon as it is in operation.

Iron and Steel.—Reports from the local iron and steel markets show that business is still improving. Increased activity in the building trades is evident everywhere. A general firming up in prices of steel was evident during the past week, several mills having made slight increases in their quotations, which have reacted locally, through forcing into the market many consumers who were awaiting the bottom level in prices to be reached.

This together with the seasonable increases has made an increase in the volume of business passing. Merchant bars are still very quiet, but there is a distinctly better tone to structural steel. Inquiries are coming in more freely, and a larger share are being converted into orders. Even those inquiries that have not so far been turned into orders have a genuine ring to them, and in many cases there is every indication that they can later be closed. Sheets and plates are more active, but no orders for rails have been received as yet, although it is expected that these will be placed this month. In some quarters considerable influence over market conditions is credited to the railways. It is commonly stated that when the railways do not come into the market, it is sufficient to warrant the smaller buyers staying out, as quotations cannot have reached their low level. Thus, although the business of the railways only amounts to about ten per cent. of the business of the country, it has an influence over purchasing to a much greater extent.

Quotations locally in all lines remain the same, and the possibility of a coal strike is making itself felt. Stocks are low, thus there is every indication that lower prices will not be quoted locally for some time at least. In the States, considerable price cutting has been taking place. During the past week, producers, jobbers, and the mills met and agreed on a standard price minimum. In some quarters there is a desire for a higher minimum, but following are local quotations:

Iron bars, base, Montreal	2 75
Steel bars, base, Montreal	2 75
Reinforcing bars, base	2 75
Steel hoops	3 75
Tire steel	3 00
Spring steel	6 00

Pig Iron.—The producers of pig iron had a meeting this week when it was expected that a revision of prices would be made, but this did not occur, the same quotations being in force. Business in the foundries has not improved, but there is a better feeling throughout the trade, and it is expected that the demand for pig iron will increase as the season advances. Just how long the existing level of prices will be maintained is hard to foretell, for producers claim there is no money in the sale of iron at present prices.

Machine Tools and Supplies.—No change in the machine tool market has taken place. The demand is light and it is only in a few instances that sales have been reported. No further changes in any quotations have been received. Business is almost completely confined to the supply end, a fair amount of business being closed. From week to week improvements are noted, but they are only nominal.

Non-Ferrous Metals.—Everything in non-ferrous metals appears to be quiet this week. No price changes have occurred and the demand is about only holding its own. For some time past there has been little or no activity in this market, but in some quarters a movement is looked for in the near future. Local quotations are as follows:

Lake copper	16 75
Electric copper	16 50
Castings, copper	16 25
Tin	34 00
Spelter	7 00
Lead	6 50
Antimony	6 50
Aluminum	23 00

Scrap Metals. — No change has been noted in the scrap metal market, prices being very weak, and the demand negligible. For several months this market has been quiet. Local quotations are as follows:

Copper, light per 100 lbs.	8 00
Copper, crucible	10 50
Copper, heavy	10 50
Copper wire	10 50
No. 1 machine composition	8 50
New brass cuttings	6 00
Red brass turnings	6 00
Yellow brass turnings	4 75
Light brass	3 50
Medium brass	4 50
Scrap zinc	4 00
Heavy lead	4 00
Tea lead	3 00
Aluminum	10 00
Boiler plate per gross ton	9 00
Heavy melting steel	3 00
Axles (wrought iron)	20 00
Rails (scrap)	12 00
Malleable scrap	12 00
No. 1 machine cast iron	19 00
Pipe, wrought	6 00
Car wheel	18 00
Steel axles	18 00
Mach. shop turnings	6 00
Stove plate	16 00
Cast boring	6 00
Steel bars, base, Montreal	2 75
Reinforcing bars, base	2 75
Steel hoops	3 75
Tire steel	3 00
Spring steel	6 00

Pittsburg

March 22.

LITTLE CHANGE has occurred in the iron and steel situation in the past week. The rate of steel production, measured in steel ingots, is about 29,000,000 tons a year as it has been for the last three or four weeks. As almost all buying of steel for many months past has been for prompt shipment, the rate of production may be taken as an index to the rate of buying, which has not changed materially for several weeks. All things considered, the rate of production is rather high for existing conditions, hence there is no ground for expecting any increase in the volume of business in the near future, or until there are decided changes for the better in underlying conditions. The advent of spring might be expected to bring heavier demand, but the high rate of production recently suggests that this influence has been discontinued. Spring affects consumption rather than production and it takes time to finish steel and put it in shape for actual consumption, so that it may be assumed the recent heavy demand has been discounting the advent of spring.

Production of Steel.—Making allowance for slight decrease in exports, the production of steel for domestic consumption has lately been running at the same rate as in 1912 and 1913, the two best years before the war, while the rate is several million tons a year above the production in the best year prior to 1912. While the demand for steel looks large by comparison with pre-war records, it looks small by comparison with the capacity, or with pro-

duction in the late years of the war and in 1920. Capacity is about 52,500,000 tons, and on this basis, the production at 29,000,000 tons, is 55 per cent. of capacity. While steel producing capacity has greatly increased since the war started, it does not follow that capacity of manufacturing consumers has increased in the same ratio. In other words, it is quite possible that consumers of steel may be quite busy without the steel mills being correspondingly busy.

The Coal Strike.—No developments have occurred reducing the prospect of there being a general suspension at the union bituminous coal mines April 1, when the present two-year scale with the United Mine Workers expires. The labor organization demands a national scale settlement as in the past, while the operators in some districts, including the Pittsburg district, have refused to meet in the former manner. The old practice was for the operators in the four states, Illinois, Indiana, Ohio and Pennsylvania, to meet and arrange a scale, scales for other districts in the country being then arranged in conformity, making certain allowances. The four states were called "the central competitive field," but this combination has now been broken up. The operators are willing to meet their employees, district by district, but the men have not consented to that.

Last week the Pittsburg Coal Producers' Association sent a formal invitation to District No. 5, the local organization of the United Mine Workers, proposing a wage agreement conference March 20, but the president of the district refused the invitation. Several weeks ago the operators published the scale they are wiling to pay beginning April 1, involving reductions of about 30 per cent. from the present high scale, and with elimination of the check-off. As matters now stand the prospect is plain that there will be a suspension, which may decrease in extent from week to week by men breaking away from the union strike order, beginning perhaps at mines on the fringes of union districts, where there are non-union districts nearby.

The coal market in general began softening about a fortnight ago and last week it turned quite soft, as to both union and non-union coal. Pittsburg district coal sold down to $1.80 for steam mine-run, when about $2.10 had been the minimum for many months, until very recently. Sellers at much under $2.00, while originally union, are supposed to have special arrangements with their men, as $2.10 is regarded as approximately representing cost with the union scale.

The trade attributes the softening in the coal market to consumers having practically completed their stocking, well in advance of the date for the suspension, the presumption being that consumers feared a last minute rush for coal, with higher prices, and wished to get through early. The steel mills exhibit no concern in connection with the prospective suspension. They are understood to have comfortable stocks, while unless there are many sympathetic strikes in non-union fields, where not a few union miners have been working lately, the non-union mines can be counted on for a great deal of coal.

It is possible that buyers of steel have been influenced in their buying policy lately by the impending mining suspension, receiving extra encouragement thereby to replenish their stocks which were at a particularly low ebb at the inventory date, thus there is a possibility of orders becoming less plentiful, rather than steel becoming less plentiful, at the beginning of April.

Steel Prices.—Regarded as a whole the steel market seems to be stiffening in price rather than declining farther, although there are some cross currents In bars, shapes and plates prices below 1.40c seems to have practically disappeared, while several mills have announced 1.50c as their price objective, a price that is very low relative to cost of production, for bars, shapes and plates had declined closer to pre-war minimum prices than other steel products.

Sheets continue remarkably firm, at 3.00c for black and 4.00c for galvanized. The latest talk among mills is that there may be an advance from the present level, the attitude being that when mills have been able to maintain these prices for more than three months, and have been getting more business lately, there is no occasion to think of any decline.

Concessions from the $2.40 price on nails, possibly down to $2.25, are being made to large buyers, but $2.40 is still regarded as "the general market." In pipe there seems to be a little less shading than a fortnight ago.

Pig Iron.—Basic pig iron has advanced 25 cents, to $18, valley, this being the third time in the past nine months it has been at that particular figure. The $18 price was established by two sales, 600 tons by the Republic Iron and Steel Company and 1,000 tons by W. P. Snyder and Company, the leading merchant furnace interest in the valleys. Foundry iron is steadier, as there do not seem to have been any concessions from $19, valley, in the past week. Bessemer remains quotable at $20.50 in odd lots. Connellsville coke has softened in general tone, following the weakening in coal, but is still quotable at old prices, $3.25 to $3.50 for furnace and $4.25 to $4.75 for foundry.

BUSINESS CONDITIONS AS GALT MEN SEE THEM

"Business is spotty, but slightly improved," is how C. K. Jansen of the Galt Machine Screw Co., sums up the situation. Speaking to Canadian Machinery regarding the sources from which orders are coming, Mr. Jansen mentioned that the automobile and wood-working fields were best of all at present, also special orders for new tools, etc. The metal working trade is not sending in many enquiries, but hopes were expressed that the wood working field would soon be ordering more freely. The latter-mentioned industry is picking up a little in some quarters, but so far the screw making trade have not felt the effect of this improvement. The majority of orders being received are of the hand to mouth variety, usually for immediate delivery. This shows that stocks are low in manufacturing plants, and that once manufacturers secure business the screw making trade will likewise benefit.

A. J. Oliver, of the R. A. McDougall Co., Galt, says that while their machine tool business is very quiet, they expect their pump trade to pick up in the spring, although small orders in place of the usual large quantities are looked for. This firm is changing over from steam to electric power, and in the near future will use steam for heating purposes only. They feel that a considerable saving will be effected by this move.

Mr. Whitehall, of the Elliott & Whitehall Co., Galt, told Canadian Machinery that they are at present working nights to close orders on time. They are working with 16 of a staff, and are securing better sales and producing more work now, than they did formerly with double the staff. Mr. Whitehall is a firm believer of going after work rather than hoping for it to come to him, and says that this is the reason his plant is busy at the present time. This firm is doing a variety of work including dies for use in automobile plants, stove factories, and other articles used in the shoe industry, etc. In addition to the above they are making their regular line of cutters and reamers, and have developed a bridge taper reamer which is said to be meeting with the approval of the trade.

S. L. Clarke, of the Perfect Machine Co., says that while they are quiet at present, he firmly believes that another two months will see things considerably improved so far as their firm is concerner. Referring to Galt itself, Mr. Clarke, is convinced that 1922 will be a good year for that city. Prospects are bright for a fairly active building season, and several residences are now in course of erection. Three firms are considering locating in Galt, in fact one of the three has decided to locate, and has bought four acres of land in the north end of the city. This firm, the International Tank and Silo Co., have an office at present in Toronto, and they plan to build a one storey factory 280 ft. x 300 ft., of "L" shape. The other two concerns are almost sure, according to Mr. Clarke, to come to Galt in the near future.

CHANGE IN TARIFF

A dispatch from Kingston, Jamaica, states that the Legislative Council has passed a tariff measure giving a preference of 25 per cent. on goods imported from Canada and Great Britain and of 50 per cent. on empire manufactured cotton piece goods.

News From the Industrial Field

The city council of Ottawa, Ont., contemplate the erection of an abattoir at the cost of $300,000.

It is reported that a representative of a Canadian firm was down in St. Johns', Newfoundland recently, with a proposition to establish a flour mill, which would employ 500 men.

An automobile factory costing $50,000 is being erected in Hull county in the vicinity of Hull, Que., by a Canadian Automobile Corporation, 197 Sparks St., Ottawa, Ont.

The total amount of construction done in Canada for the month of February 1922 totals $10,718,300. Nearly seven million dollars of this was spent on industrial work.

The daily output of the Durant Car Co., of Leaside, Ont., has increased to nearly 25 per day since the first of March; 4,000 cars are expected to be finished by the first of July 1922.

The Canadian Car & Foundry Co., of Montreal, has secured an order from the C.P.R. for 50 compartment and 3 refrigerator cars.

It is estimated that the C. N. R. has between 5,000 and 6,000 cars that need repairs, overhauling, etc.

The Boiler Engineering & Equipment Co., dealers in boiler compounds and used boilers, of 222 Craig Street, West, Montreal, have moved to new quarters, 68 Prince Street, Montreal.

Actual gain in cash position of Canadian foreign trade is stronger by $150,000,000 than 12 months ago.

The Fulled Brush Co., has installed new machinery and equipment in their plant at Hamilton, Ont., for the manufacture of their product.

The Canadian Pacific Railway Co., is reported to be negotiating with the Port Arthur Shipbuilding Co., for construction of a large lake passenger ship.

The Enterprise Foundry Co., Sackville, N. B., is reported as stating "Our main plant is running full time with about 80 per cent. crew. This applies to our foundry department as well as all others."

Kerr and Goodwin Machinery Co., Brantford, have recently shipped three carloads of the "Brantford" oil engines to England. Other shipments have been made recently to South America and the British West Indies.

The J. S. Rose Co., state that the item which appeared in our January 26th issue to the effect that they had discontinued their Toronto office was incorrect as they still hold stocks at their office in the Page Bldg., Toronto, and are still meeting the requirements of the Canadian trade.

A report from Washington states that there is a possibility that industries in the states may open negotiations with Canadian coal companies for their requirements, if the strike in American coal fields takes place.

An encouraging factor of present conditions is the steadily growing activity reported in the building industries in Toronto. It is expected that some large construction jobs will commence in the near future.

Orders for iron ore, approximating three of four hundred thousand tons, have been received by the Dominion Iron and Steel Co., to be shipped from Wabana to steel companies in Europe.

The Lymburner Brass Works, Inc., 1025 Boyer Street, Montreal, Que., want complete equipment for a brass foundry.

The Central Machine and Welding Co., 38 Bromston Lane, Montreal, Que., is in the market for a welding machine and small lathe.

The F. T. Hill & Co., Markdale, Ont., is in the market for modern flour mill equipment to replace that which was destroyed by fire. Estimated loss $35,000.

The plant of the Blystone Manufacturing Co., manufacturers of sand sifters and other foundry equipment, at Cambridge Springs, Pa., was recently destroyed by fire. A new factory will be erected immediately.

Construction of a four storey addition to the building of the Great West Life Assurance Co., Winnipeg, Manitoba will be begun immediately. The addition will cost $300,000. The work will be completed by October 1st, 1922.

The demand for Canadian paper by United States users shows a steady return to normal according to a report issued by the Canadian Pulp and Paper Association. Most of the Canadian mills are now working in about 90 per cent. of their maximum capacity.

A large addition to cost about $150,000 will be added to the University of Ottawa building this year. Completed plans for its erection are now in the hands of contractors and work will likely commence in a month.

The waterworks commission of Brantford, Ont., is having plans prepared for an addition to the pumping station to cost $250,000, including the installation of three gauge centrifugal pumps with electric motors.

The Empire Cotton Mills, Welland Ont., have decided to erect dye mills adjoining their present plant at a cost of $200,000. A by-law will be submitted to the ratepapers granting the company certain concessions.

At a meeting of vessel owners at Kingston, Ont., it was decided to reduce freight rates 35 per cent., for the Cleveland navigation, which opens with the break up of the ice. This announcement was made by J. S. Sowards, one of the prominent marine men of the city.

Announcement has been made of the appointment of C. R. MacKenzie to the position of assistant to the vice-president of the financial and accounting department of the C. P. R. at Toronto. Mr. MacKenzie has been assistant to the general manager at Montreal, since 1918.

The city of Toronto proposes to spend about $7,000,000 in municipal undertakings during 1922. Included in the estimate just compiled by the Works Commission is an item for additional pumps and extension of reservoirs to cost $1,060,000.

If the course of exchange be true augury of 1922 eventualities the Canadian outlook is 100 per cent. better than a year ago. The new year opened with Montreal dollars at 5 per cent. discount. The old year began business with Montreal dollars worth 85c a piece in New York.

The Perfect Machine Co., of Galt, Ont., reported "Business is fairly good, at least 100 per cent. better than the winter of 1920 and 1921. Our foundry has been busy all this winter and orders are on hand which will be sufficient for possibly another month."

Some good orders have recently been received by the Horton Steel Works, Bridgeburg, Ont. In connection with the sprinkler system in the Canadian Libby-Owens Sheet Glass Co., new plant at Hamilton, they have completed the installation of an elevated tank of 50,000 gallon capacity and 75 feet high.

Largely through the instrumentality of the British Columbia division a large order for wood conduit piping being placed reeently by the B. C. Telephone Co., was retained in Canada. It has been intimated that the company had intended to place the order in the United States. The order is for over 15 miles of conduit, which will require more than 250,000 ft. of lumber.

At a meeting of the Board of Directors of the Ford Motor Co., of Canada, Mrs. Gordon M. McGregor, wife of the late first vice-president, was appointed a director to fill the unexpired term of her husband. Wallace R. Campbell, who for some years has been secretary and assistant treasurer, will succeed to the position of first vice-president. and treasurer. Mr. Campbell's old position will be filled by P. W. Grandjean, assistant secretary.

The Boston Blacking Co., have just finished installing new machinery in their plant at 152 McGill St., Montreal, by which they have nearly doubled capacity. They are now engaged in enlarging their cement plant at Cote St. Paul by putting in new boilers and other machinery and improvements.

Machinery is wanted for Guatemala industry. It is reported that a company has been formed in the republic of Guatemala with the object of establishing plans for the manufacture of jute fabrics, and allied products. Those interested should address the Central and South American Export Company of Guatemala, Guatemala, Central America.

Speaking recently on unemployment in Canada, Hon. James Murdock, Minister of labor, stated:—"I see it is easing up, and I am glad to say that the gentlemen who are directing big business in the country are showing every disposition to assist all they can in creating employment. I look for the breaking of spring and the finer weather conditions to help considerably."

An interesting story comes from Iroquois Falls the home of the Abitibi Power Co., Montreal, which illustrates the real improvement and the demand for newsprint from the United States. A special train of 50 cars loaded with paper was dispatched on March 10th from the Falls to Chicago for the printing of the Monday issue (March 13) of the Chicago "Tribune."

Trade in the small tool and supply business continues to improve in Canada and is bound to improve as the season advances. The increase in building is helping the tool trade. Should general building operations develop as promised it will stimulate activity in many lines of manufacture which supply materials.

Fire breaking out in Picton, Ont., on March 12th, from an unknown cause totally destroyed the planing mill, stables, flouring and grist mill of Messrs. Hyatt & Hart. The loss is placed at $20,000 partly covered by insurance. The greatest loss is on the machinery. Only last fall this concern installed a new flouring mill.

H. J. Logan, member for Cumberland, has notice of a resolution on the order paper that all goods to receive the benefit of the British preferential tariff rate must be imported through a British port. This proposal has already been discussed before and advocated by the Maritime Provinces Board of Trade. It will affect a very large proportion of Canadian imports.

The Durabla Manufacturing Co., of New York, manufacturers of Durabla gaskets announce that the first shipment of Canadian made Durabla goods are going out this week, following the expenditure of $30,000 in a Canadian plant to meet the demand for Canadian made goods. Durabla gaskets will be sold in Canada at the American price under guarantee to perform the work it is sold for or money refunded.

It is believed that the Montreal Public Service Corporation contemplate developing power on the Chippawa River, Pontiac County, where 90,000 H. P. can be generated. This corporation is seeking power to construct transmission lines in 23 counties in the province of Quebec.

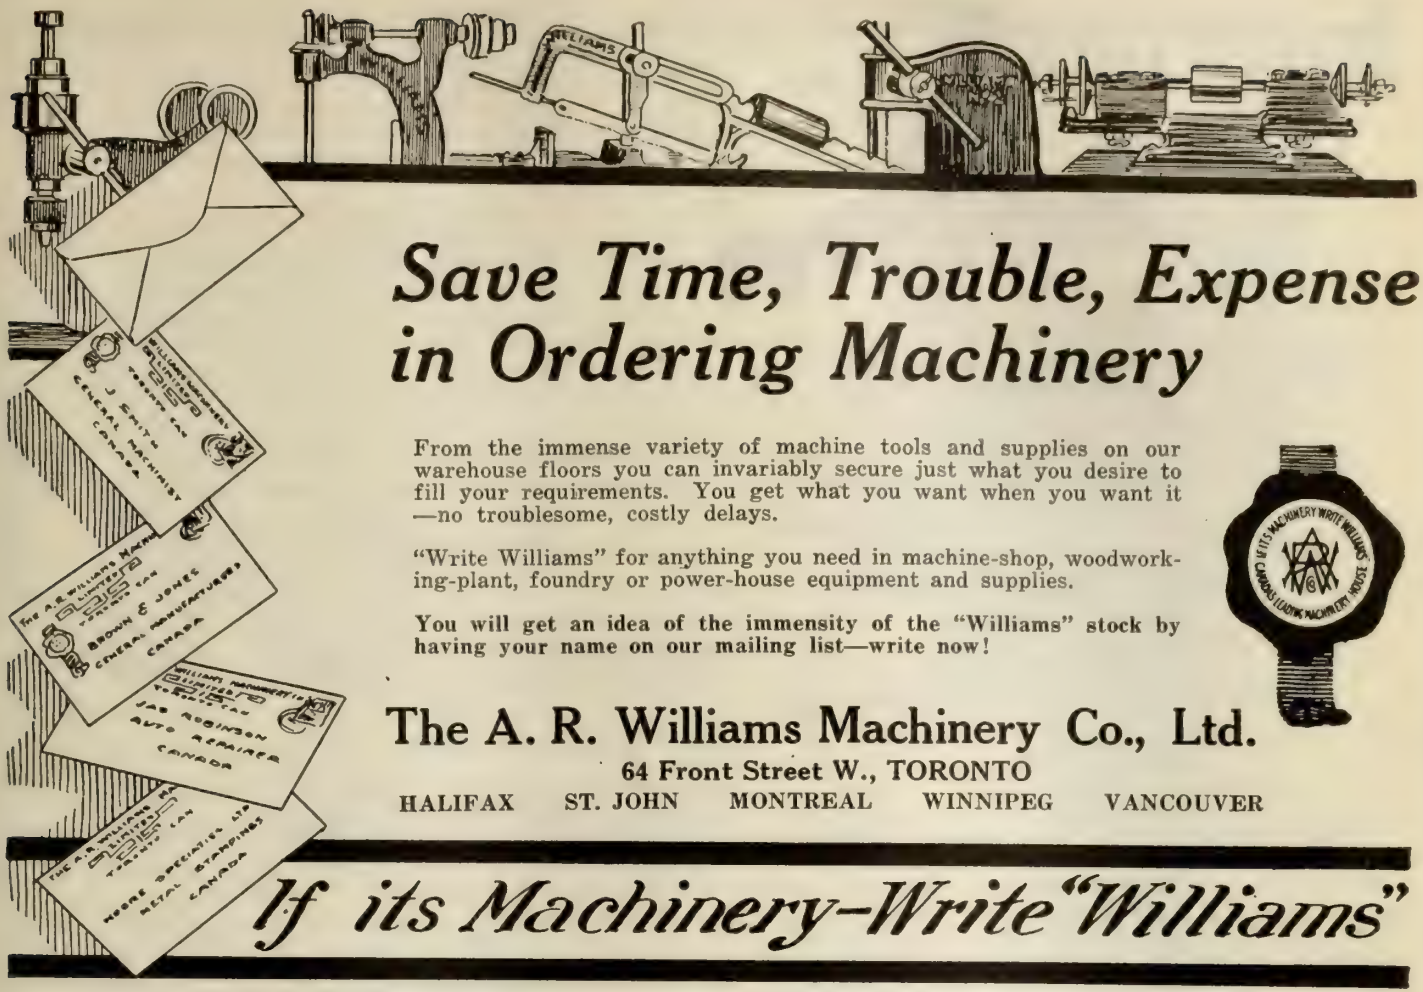
S. Webb, Canadian Trade Commissioner at Buenos Aires, reports prospects for Canadian trade in the Argentine are brighter than at any time during the past year, owing to the falling exchange rate, improved position of export trade and increasing number of inquiries from Argentine importers.

It has been stated, that the Durant Motors of Canada are to erect an addition to their present plant at Leaside, Ont., which will make that town the location of one of the largest automobile plants in the Dominion. The new building is to be completed by early fall. With the addition the whole plant will cover an area of 28 acres and will employ a force of nearly 3,000 men, as compared with the 600 at present engaged. 50 cars per day will be the output.

The Canadian Rampo Iron Works, Niagara Falls, Ontario, manufacturers of railway switches, crossings and switch stands, are making extensive additions to their plant. Considerable new machinery has been installed and a new building is planned, representing, it is understood, a total outlay of about $100,000. Exceptional activity in railway construction is anticipated.

The Hayes Wheel Co., Chatham, Ont., is making an effort to secure business with British automobile firms who are in the market for 20,000 chasses during the present year. The manager of the Chatham company has left for Britain to negotiate business. The British motor car manufacturers intend to press their export business more strongly especially to other parts of the British Empire.

A new industry is to be established in St. John, N. B. as a result of the decision of the town and council of that city, to award a large contract for cast iron pipe to a local company which promised, if they secured the contract to establish a foundry, and make the pipes in the city as the beginning of a new industry. It is promised that the work will be extended to a point where employment will be given to from 160 to 200 men.



H. Graham, general manager of the Bond Engineering Works, Toronto, has been in England for the past six months, and brings back with him some first hand information regarding conditions in Great Britain. In conversation with Canadian Machinery he said that the textile trade seemed to be picking up slightly, but that the engineering branches, especially the shipbuilding and machine tool business was very dull indeed. Mr. Graham touched upon the present labor trouble and mentioned that it was particularly unfortunate at the present time when Britain was trying so hard to get properly on its feet. Woolen goods were picking up, but this improvement was confined to the finer grades. Mr. Graham feels however that it is only a question of time before Great Britain manages to master these labor difficulties, when they will once more take their proper place in the commercial world. Speaking about his firm's activities in Toronto, he said that they are doing all in their power to improve their lines, wherever possible, and were taking this opportunity of preparing for the increased business which will come when general conditions improve.

Two industries of considerable importance are negotiating for location in Welland. One would manufacture seamless steel tubing such as is used for boilers, and would take over the building and plant of Welland Machine and Foundries which would be considerably extended, and the other would acquire the building and plant of Electric Steel and Metals, which has been lying idle for some time, and would use it for foundry and rolling mill purposes. No details are as yet ready for publication.

Contract for the construction of four steel cargo ships has been awarded to Fraser, Brace & Co., Montreal, for the work to be done at Three Rivers, Quebec. The ships are to be coastwise coal freighters, for the George Hall Coal Co., of Montreal. The vessels will be 250 feet in length between perpendiculars, with 43 ft. molded beams. They will be built partly on Isherwood plan. Each ship will be equipped with electric lighting plant and refrigeration system of a type not yet decided upon, and will start in June.

Speaking about history please note the following: The first Canadian cheese factory was established in Ontario in 1864 and the first Canadian Creamery for butter making in Quebec in 1873. The first centrifugal cream separator was imported from Denmark in 1882 and the Government organization of cold storage services dates from 1895. According to official record the number of dairy factories operating in Canada in 1920 was 3,161, comprising 1,045 creameries, 1,683 cheese factories, 405 combined butter and cheese factories and 28 condenseries.

The directors of the Steel Company of Canada at a meeting held in Montreal on Friday, March 17th, declared the regular quarterly dividends of 1-3/4 per cent., upon both the preferred and the common shares of the company. President Robert Hobson, who was present from Hamilton for the meeting, briefly commented on the business outlook to the effect that conditions are gradually improving. He gave no intimation that anything of a boom is expected, contenting himself with the above statement. The annual meeting of the company will not be held until the middle of April, at which time the figures of the company for the current year will be announced.

Save Time, Trouble, Expense in Ordering Machinery

From the immense variety of machine tools and supplies on our warehouse floors you can invariably secure just what you desire to fill your requirements. You get what you want when you want it —no troublesome, costly delays.

"Write Williams" for anything you need in machine-shop, woodworking-plant, foundry or power-house equipment and supplies.

You will get an idea of the immensity of the "Williams" stock by having your name on our mailing list—write now!

The A. R. Williams Machinery Co., Ltd.
64 Front Street W., TORONTO
HALIFAX ST. JOHN MONTREAL WINNIPEG VANCOUVER

If its Machinery—Write "Williams"

The Lion and The Mouse

DO YOU remember reading in the school books about the great big lion who was caught and trapped in a gigantic net by hunters? Then along came the little teeney mouse who nibbled away at the netting and was successful in setting the lion at liberty again. The net was too strong for the lion to break but the constant nibbling of the mouse, breaking mesh after mesh, was able to perform the seemingly impossible.

A person who is not subscribing to CANADIAN MACHINERY is in exactly the same circumstances as the lion imprisoned in a corner—not being able to enjoy the freedom of expanding his capacity for knowledge.

CANADIAN MACHINERY acts as the mouse. Week by week it will give information —which, on account of the lack of it, has tied you up in an industrial way—will nibble away the meshes, one at a time, that are keeping you from getting the results you want.

Ask us to send you a sample copy. It will not obligate you and it will be a pleasure to us.

CANADIAN MACHINERY,
143 University Ave.,
Toronto, Canada.

Please send me a sample copy of your paper and oblige.

Hamilton Gear & Machine Co.

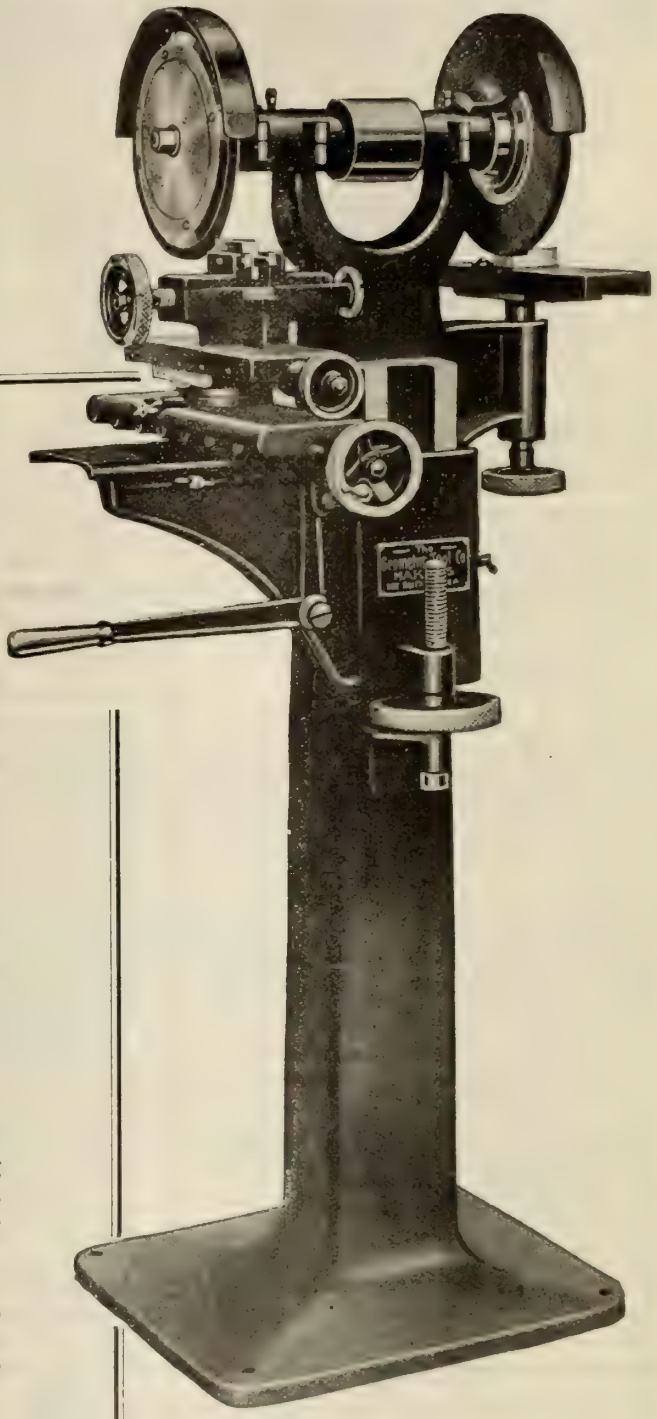
76 Van Horne St. - TORONTO

A report from Sarnia, Ont., states that the Pere Marquette Railway Co., plan the erection of a $350,000 bridge of the jack-knife type, over the Black River to replace the present draw bridge in that city. It is proposed to commence actual construction work on this structure this year.

Road construction is brisk at present not only around Toronto and this part of the province, but it is the same in practically every province of the country. The Province of Ontario is working on a large program of something like 1,800 miles of new or re-constructed road to be spread over a period of five years. An index of this possibility lies in the fact that in about 10 years the number of motor vehicles licensed in the province of Ontario has increased from about 25,000 to 250,000 and there is today about one vehicle to every eighteen inhabitants of the Dominion, or about one to every three families. This means a great impetus and demands not only for road building but also the manufacture of motor vehicles for passengers and freight, and in these respects engineering activities are very marked at the present time.

INSTRUCTION LARGELY OF INDIVIDUAL KIND

(Continued from page 30)



heavenly body above the observer's horizon, with a sextant.

Magnetism—laws relating to both permanent and induced magnets and the disturbing influence they may have on the compass needle when placed on board ship, and how that disturbing influence can be counteracted by placing permanent and induced magnets around the compass.

Seamanship—including the manoeuvring of vessels under all conceivable conditions; stowage of cargo; and ship construction. Signalling, by flag and Morse.

The instruction is for the most part individual, a few of the subjects being handled by the lecture method. Up to the present fifteen have been successful in passing their examination as chief officer for inland water vessels, five for master inland water vessels, four for master coasting trade. In addition to this several pupils are attending the class to educate themselves for the higher grades of their profession, so that they may be prepared to take a step higher when they can produce the service necessary for that advancement.

The marine engineering classes are designed to give the academic side of the training necessary for the examinations for the various classes of marine engineers. The requirements for these examinations are given in regulations, relating to the examination of engineers, issued by the department of marine, Ottawa. In these classes, instruction is individual.

Sharp Chasers Cut Clean Threads

Accurate, uniform threads result only from dies which are maintained in the highest state of cutting efficiency. This means that chasers must be kept sharp, and ground uniformly.

Even if just touched up from time to time, the chasers respond splendidly, with clean threads. And with this machine—the Geometric Chaser Grinder—the matter of keeping threading tools up to scratch is a comparatively simple matter.

Any make of chaser can be ground on this adaptable machine. The two wheels permit the easy grinding of both milled and tapped chasers. In addition, the plain wheel lends itself readily to various kinds of tool grinding.

Uniform grinding of a set of chasers is purely a mechanical matter through the use of adjustments which can be accurately set to govern the grinding of an entire set of chasers.

The Catalog describing this machine is a mine of information on chaser Grinding. Write for it.

List of Directory of Dealers will be found above Advertising Index

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

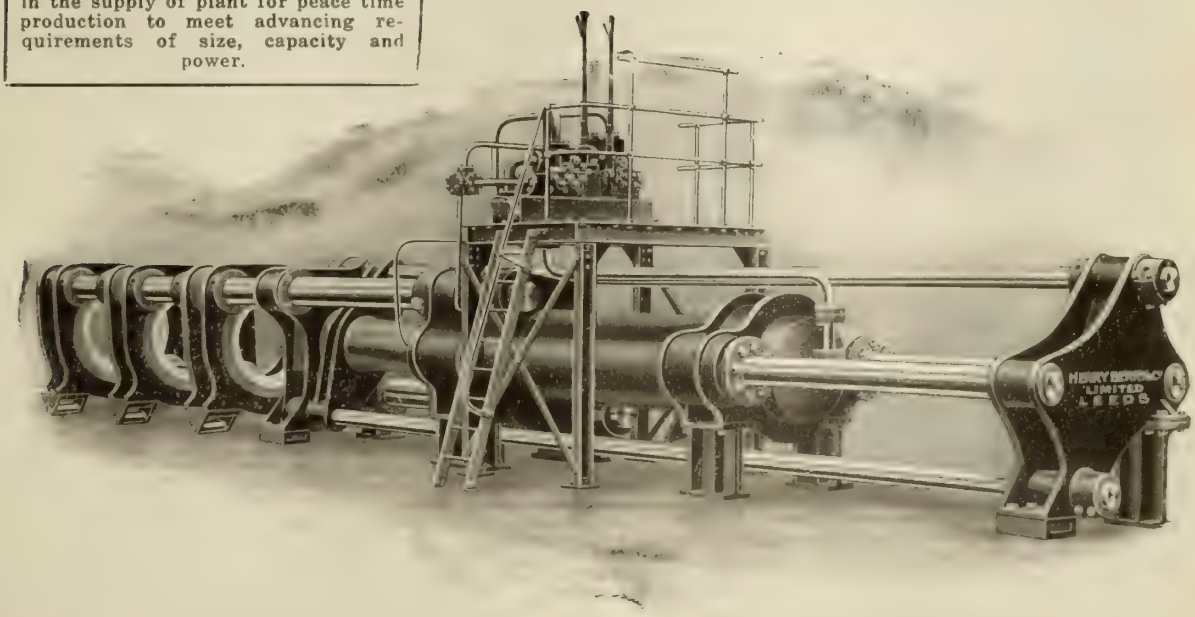
Messrs. Fairbanks-Morse Company, Limited.

Head Office **—Montreal**



A Cradle Of Imperial Industry

Concerned for many years with the design and the manufacture of some of the largest types of machinery for the British Government, the Colonies and the Indian Empire, the firm of Henry Berry & Co. possesses some of the most extensive resources in the country for the production of the biggest, most powerful and most practical types of hydraulic machinery for Shipyards and Industrial Enterprises. These include all kinds of Shipyard Tools, Plate and Armour Bending Rolls, Rivetters, and Punching and Shearing Machines, Presses and Cranes.

Designs and estimates will be submitted to all requirements without charge. Prompt deliveries with full guarantee of Quality and Power.

750 TON PUNCHING & DRAWING PRESS

Pioneer manufacturers of hydraulic shell forging presses for the largest shells in use during the Great War, we are likewise always to the fore in the supply of plant for peace time production to meet advancing requirements of size, capacity and power.

Keep Your Factory Safe
For Your Men and for Yourself

The factory that has Dennisteel Individual Lockers for the personal belongings of the employees has removed the cloak-room evil. No more gathering of smokers in an unsupervised place; no more danger from lighted pipes left in pockets. If a pipe is left lit it harms no one's property but its owner's, for each locker is an individual cloak-room. The feeling of privacy the locker gives your employees promotes contentment.

More Dennisteel Lockers are being installed to-day than ever before.

DENNISTEEL
Made in Canada

Lockers and Cabinets
For Schools, Factories and Offices

What a Dennisteel Cabinet Does for Your Office

The Dennisteel Cabinet provides a place for stationery, supplies, books, etc., that keeps them from dust, vermin and fire danger.

It utilizes little space, yet provides plenty of room for the storing of the supplies required by most offices.

Above all, it promotes system. When you have your office books and supplies in a Dennisteel Cabinet, you know just where to lay hands on them.

Dennisteel Cabinets are a handsome article of office furniture. Shelving and pigeon-holing can be arranged for individual needs. Standard finish of olive green. Can be finished to harmonize with other furnishings if desired.

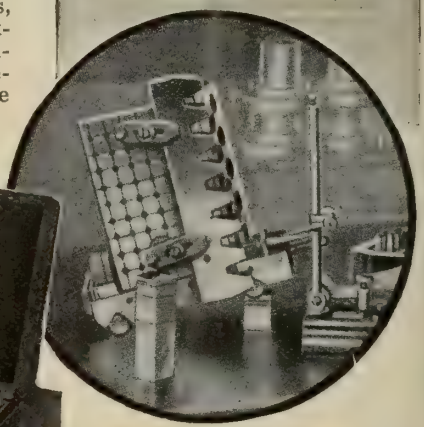
Laboratory Accuracy at a Toolroom Price

A TRIAL of Hoke Gages under your own conditions will convince you that our claims for these blocks are justified. You take no risk —the Pratt & Whitney guarantee is broad enough to assure satisfaction. The price permits the use of Hoke Blocks in every-day toolroom work. A reference set laid away in the safe is not earning for you what it should.



The Story of Hoke Gages—

A Booklet that will Interest You

Using a stack of Hoke Gages for checking profile on a Maag Gear Cutter.

This interesting catalogue will be sent on request to Manufacturers, Superintendents, Engineers, Inspectors, Tool or Production Foremen, and others who want to KNOW. It contains information covering — Gage Blocks, Registered and Identified; Means of Identification; Guaranteed Reliability; Advantages of Square Design; Reason for the "Hole"; Various Combination Sets; Attachments and How to Use Them; Some Every-day Applications — Testing Tapers, Scribing Lay-outs, Checking Profiles, etc.; Toolmaker's Flats; Mikechecks; Swedish Type Gages.

Details, prices — all the information you want — are yours for the asking.

BOWSER ESTABLISHED 1885

Friction is the Thief of Power

Friction is a consistent liability. Then why keep it on your payroll? That is exactly what you do when you do not handle and filter your lubricating oil properly.

Bowser Oil Filtering Systems reduce friction to a minimum and obtain the highest economy in operation, and in the use of lubricating oil. The patented Filter takes all water and sediment from the oil and makes it clean and ready for use again.

Consult Bowser Engineers—they can solve *your* lubrication problem.

Increase the Consumer's Interest

Create a Livelier Demand for Machine Shop, Power House and Foundry Equipment

ARE you manufacturing equipment for Machine Shops, Metal Working Plants, Power Plants and Foundries? Does the consumer know your products? Does he know their quality sufficiently to insist upon getting them when he places an order with his hardware dealer? Carefully weigh these questions. Then consider the advisability of reaching the consumer through the columns of MacLean Technical Newspapers. You can probably use one of the following group.

CANADIAN MACHINERY AND MANUFACTURING NEWS—issued weekly, serving the Canadian Machinery, iron, steel and general metal-working industries: it is read by the men who buy equipment, proprietors, purchasing agents and other executives: its editorial contents are authoritative and comprehensive.

POWER HOUSE—published twice a month, serving steam, electrical, water and gas power plants, in addition to refrigeration plants, in all parts of Canada. It, too, reaches the men who buy equipment; it, too, is the leading authority of the Dominion in things pertaining to its field.

CANADIAN FOUNDRYMAN AND METAL INDUSTRY NEWS—published monthly, rendering indispensable service to the grey iron, steel and non-ferrous foundries of the country. Proprietors, executives and foremen read it diligently.

You can awaken new interest in your products by advertising them to the consumer through MacLean Technical Newspapers. Write for complete information.

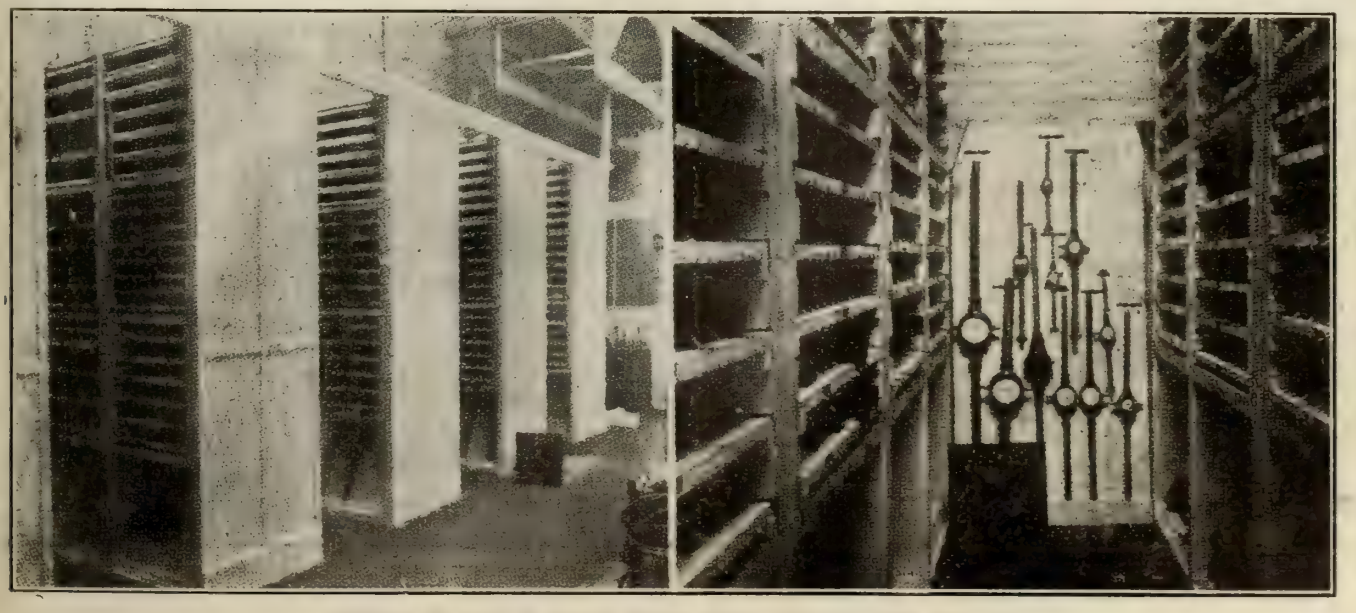
Protect Your Cutting Tool Investment

Suitable Racks and Storage Facilities Should be Provided—Workmen Should Recognize Need of Careful Handling—Speed and Feed Important—Ample Chip Clearance Should be Provided

By H. ALTON



THE MANNER in which edged tools are cared for is so important that the success of a shop can almost be judged by the extent to which this factor enters into the administration of its affairs. Even the small repair shop employing a few men, has its tool problems, although in many instances it does not realize it. Then we can jump to the other extreme and consider the highly specialized modern shop manufacturing, on an interchangeable plan, thousands of similar articles. Here tools occupy the attention of a highly specialized department. In a nutshell every machine shop has a certain number of tools, and as they represent an investment, upon which returns must be made, they must be cared for not only while they are actually doing work on a machine, but also during idle periods.

Small Shop Practices

Many small shop foremen do not give the tool problem the attention it deserves. Take the shop where a general line of repair work is done. Here one usually finds in general use on the lathes, shapers and planers, a fair number of tool holders. Somewhere in the shop you will find a few bars of hardened carbon tool steel ⅜ in., ½ in. and ⅝ in. square, with an occasional odd bar of high speed steel. Probably the practice in the shop, is that when a man has completed a job on a machine he removes the tool bits from the tool holder and places them in his private tool box, considering them his own property. The reason that this practice is so common in this type of shop, is probably because each man grinds his own tool bits and believes that the clearance and rake angles that he places thereon, being largely guided by the "feel" of the tool against the wheel, and the "look" of it afterward, are especially adapted to removing metal, and he further feels these tools should be set up by himself. The interesting feature of this practice is the almost universal distrust of tools ground by the "other fellow." Thus in a general way these tool problems take care of themselves.

Use and Abuse of Twist Drills

From the lathe and the planer, let us go over to the drilling machine. There are many examples of thoroughness shown in the care meted out to drills in the small shop, but then, we too often run across gross carelessness. Some examples of the latter may be seen in the miscellaneous collection of twist drills, from ⅛ in. diameter up to 1 in. or larger on a shelf or in a box without any attempt being made to preserve the cutting edges or to arrange them as to size. In examining the drills we discover most of them to be carbon steel with an odd one or two high speed drills here and there. Every time a drill is selected, dozens of drills must be handled and finally when the correct size is found the dozen or two drills not required are carelessly tossed back. This treatment is disastrous to cutting edges. Sizes become obliterated, and then time is lost in determining proper sizes. It is also bad practice to place the point of a revolving drill against a piece of work and neglect to start the feed. If the work happens to be cast iron, from which the scale has not been removed, the effect is even worse. Loose chucks that permit the drill to drop out at unexpected moments are also a menace to cutting edges in two ways; the first, that the falling drill

Showing the value of making suitable storage racks for tools, dies, etc.

coming in contact with a hard substance has its point and cutting edges damaged. and second, a mechanic who will put to work a chuck that functions so indifferently will not usually have any scruples which would prevent him from applying a steel hammer to the nose of the drill in an effort to force it far enough into the spindle to bind. Then too, the writer could never understand the line of reasoning that prompted shop men to purchase small letter and number sizes of drills, whose diameters were expressed in thousandths of an inch, and larger drills in 1/64 of an inch dimensions and then allow any of his employees to sharpen these drills on a plain emery wheel. Angles of clearance are not maintained and often a half inch drill will make a 17/32 in. diameter hole after such grinding. All these factors have a very direct bearing on the life of the cutting edges.

Drilling Grey Cast Iron

In many cases, when drilling in grey cast iron, no lubricant is necessary for the drill. In fact drills usually perform to much better advantage when no lubricant is applied. When a drill has a proper edge, the clearance angle is correct, the speed and feed are reasonable, and one readily recognizes the characteristic chips that are produced. They remind one of the chips produced by a very sharp wood bit boring a hole in a piece of soft pine. Of course, as the drill goes deeper into the metal the chips produced are forced up through the spiral flutes of the drill and are more or less broken up. Sometimes in certain lines of work the chips clog and cause the drill to heat. This condition of affairs is usually automatically announced by the "squeaking" of the drill. The dust present in cast iron chips works in between the full diameter of the drill and the sides of the hole. When this occurs the hole is usually found to have a ragged appearance and is more or less enlarged and out of round. Lubricants will not remedy such a condition but rather tend to aggravate it. It is necessary to nip this trouble in the bud, and when drilling deep holes in cast iron, if your drill is vertical, always withdraw the drill from the hole and clean it out as soon as it is noticed that chips appear to come from the hole less freely than they did in the first inch or so of the drilling, and do this as frequently thereafter as judgment suggests. When short drills are used it is practically impossible to sink the drill below the flutes which provide chip clearance. Results are always unsatisfactory when this is done.

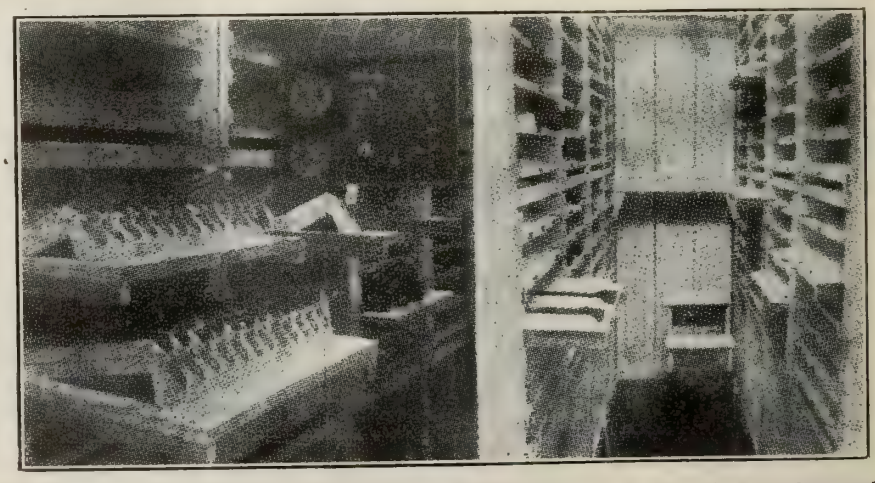
Drills may be driven at too great a speed. This form of abuse is sometimes present in production shops and is frequently found in contract work shops. The following is an incident that is enacted daily. A mechanic goes to the radial drill and wants to drill a couple of tapping holes for a one inch tap. He finds the back gear out and the belt on the cones in such a manner as to give next to the highest speed. (The man that preceded him was using a quarter inch drill.) Now as the holes that are to be drilled are only in grey cast iron through a flange about one inch thick, the drill is placed in the chuck and spindle and the power applied. In nine cases out of ten the drill is a carbon drill and its "temper" is drawn. In contract shops carbon drills are usually more in evidence than high speed drills. These shops, of course, have in stock a good range of high speed drills but these drills are always kept under much closer supervision in the tool stores. Hence in emergency jobs of a petty nature carbon drills are abused. From their very nature, high speed drills can take care of more rough usage without undue injury, than carbon drills. But we cannot evade the fact that hardened steel is necessarily brittle and undue rough handling does not in any way add to the life or to the usefulness and efficiency of a drill.

Twist Drills in Steel

The drilling of holes in steel does not vary fundamentally from the drilling of cast iron. In steel, however, lubricants are essential. The general practice is to use more high speed drills in steel than in cast iron. The chips produced by a properly ground drill working in steel, also have characteristics that are easily recognized. The chips appear in long curly pieces, and generally speaking, the hole in steel is cleared of chips automatically to much better advantage than in cast iron, as there is absent the large quantity of dust-like chips. Properly ground drills will maintain their edges in steel for a remarkably long period, if driven at proper speeds, given reasonable feeds, and supplied with a proper lubricant in sufficient quantities at the proper place, which is the cutting edge. Lard oil forms the base of most of these cutting lubricants. In fact a large majority of the soluble oils on the market today are substitutes for lard oil and have a certain percentage of it in their make-up.

Drilling Holes in Plates

A punch is not always available and it is sometimes necessary to drill holes in sheets or plates. It is often hard to clamp such material securely under a drill. When breaking through, if there is any lost motion in the spindle, the drill will in all probability be broken, if it is of a small diameter. Blocks of hard wood should be placed under the plate at the point where the hole is to be drilled, and then the feed should be finally made by hand. It is a good practice to keep all lost motion of drill spindles and to be careful at all times when the drill is "breaking through" whether drilling in cast iron or steel. On the old general purpose radial drill when the head is out at the end of the arm even if the lost motion of the spindle is negligible, there is enough spring to make "breaking through" disastrous to small diameter drills.



Clamping Drill Work

Better results from drilling are always obtained when work is firmly clamped. In production work jigs and fixtures are usually provided which permit the work to be securely held. It is in the case of the small odd job that clamping is neglected and trouble arises. If a piece is held in the hand and the drilling started, more often than not, the piece is torn from the hand and spins under the drill scattering odds and ends of loose pieces all over. Clamping should never be neglected as many drills are broken and many more have their cutting edges ruined through this cause.

Drilling Non-Ferrous Metals

Now and again there crops up a job that necessitates the drilling of a hole in copper, babbit metal, lead, etc. In most cases drills ground to do good work in iron and steel do not perform satisfactorily, no matter how keen their edges may be in non-ferrous metals. Brass is about the only exception. Iron and steel-working tools usually perform satisfactorily in brass and can be operated with no ill effects at very much higher speeds.

Returning to copper, it is not usually economical to grind a drill especially for this work and generally we worry along with a drill ground for operating in iron and steel. Some mechanics recommend turpentine as a cutting lubricant. Some advise other practice. The writer has found that when a drill is ground with little clearance and an attempt made to

It is often a good plan to arrange tool shelves so that they slide out as shown in both photographs.

give excessive rake that good results in copper can be obtained without any lubricant and at no mean rates of feed and speed. Babbitt metal presents many difficulties owing to its nature. It is difficult to clear chips from anything but a shallow hole if a twist drill is used. If the hole required does not need to be drilled to extremely close dimension use a flat drill.

Taps and Dies

Taps should be used much the same as drills. They should be used dry in cast iron and with lubricant in steel. Owing to the design of a tap it should have complete protection at all times as its cutting edges are easily ruined. As soon as the land of a tap is ground off it is impossible to maintain its size and its usefulness is ended. Hand dies have their cutting edges more or less protected by their design, but careless use of dies has its bad effects. Dies in a die head on a bolt cutter or pipe threading machine usually receive a fair amount of consideration.

Solid Lathe and Planer Tools

Every shop has an accumulation of solid lathe and planer tools. It is an unfortunate fact that you will often find these tools scattered under the various machines, or mixed up with plates and straps in boxes, cabinet legs or in miscellaneous cupboards. It is difficult to explain why such tools, which often represent quite an investment, are not given better treatment. Their cutting edges yield to harsh usage in the same manner as do more delicately designed tools. A little care in placing these tools out of harm's way when a job is completed would save many a little slip of the cutting edge. The time consumed in grinding a new edge on the tool before it can be used again, and also the time spent in looking up a tool carelessly put away, are luxuries too expensive to be enjoyed under present conditions.

Milling Cutters

The milling cutter is an expensive tool to make, and considering its design, it is one that stands for a great deal of hard usage. Not only are milling cutters expensive from a point of view of first cost, but also when a milling cutter becomes dull it is an expensive item to sharpen it, if all items are considered. True it is, that modern milling cutter grinding machines make the job a short one. But these grinding machines are not only expensive, but there is the difficulty of keeping these machines busy and usually the carrying charges to be borne, per sharpening, are heavy. A milling machine operator who thoroughly understands how to get the most out of his cutters between grinding is a real craftsman. When roughing jobs are to be done, in no case should a high grade finishing cutter be employed. Speeds should be studied, and feeds understood. Work should be properly clamped and all necessary parts locked in place. A good supply of cutting lubricant should be distributed over the entire surface of the cutter. In all cases of side and face mills a copious flow must be maintained or else several streams of liquid provided. Chatter should in all cases be eliminated, as it is disastrous to the finely ground milling cutter. Every support should be given the arbor, bearings should be properly maintained and work fed at proper speeds. A cutter should not be backed over work. The table should always be lowered a trifle so that the work can pass freely under the revolving cutter.

The application of the milling principle has been made to large machines for railroad and heavy manufacturing work. Slab millers and large facing machines employ huge milling cutters with inserted teeth. The centres of these cutters are not high speed tool steel but are often made of carbon tool steel, or high carbon forged steel. They are not hardened. The sharpening of the large milling cutters is an expensive process. However, the relatively large number of teeth and the comparatively slow cutting speed enable the cutters to remove a large quantity of metal between grindings. No specific instructions can be cited as applicable to this type of cutter. Care and common sense will provide the necessary measures for preserving the edges.

Hack Saw Blades

The humble little hack saw blade always comes in for an unusual amount of abuse. The hand power saws never wear out, they are always broken, when just in their prime. By the use of mere words it is difficult to convey the idea of the methods that it is necessary to practise if the life of the hand saw is to be extended. The saw blade must be guided straight and not allowed to bind. Even pressure must be maintained on the cutting strokes and the operator of the saw must keep his eye on his work. In the case of the power hack saw, the blades get a better opportunity to do useful work over a longer period. But even here it is often noticed that blades are minus an odd tooth or so which greatly cuts down the speed of cutting.

The File

The file is an edged tool. The point of each tooth on it is as beautifully sharp as the edge of a good chisel. If the tool is carelessly handled some of these teeth are broken, with the result that the next time the file is used it seems dull or makes furrows or ridges in the work. Do not throw files carelessly into a drawer with cold chisels, hammers, and other hard objects. It is bad practice to leave files lying around on the bench or lathe where they are quite apt to be swept on the floor and broken. Hardened steel is necessarily brittle and all files are as highly tempered as is practical. Files kept in a damp place will rust and rust will ruin the best tooth ever cut on a file. A good mechanic will not use a file for any other job than that for which it was intended. The expression that "it is only a file" is often made use of to justify the abuse of the tool. Many shops that appreciate the value of a file provide racks for them when they are not in use.

Conclusion

The whole problem of how tool edges become damaged can be boiled down to the statement that damage is caused by the carelessness or ignorance of the mechanic, and shop owner. A good mechanic will always give consideration to his tools and when a job is finished he will put them away carefully. A good shop owner will provide good tools, choose competent and trustworthy men to use them and provide good tool storing facilities for the tools when they are not in use. He will see that the storage bins and racks are not in a damp place and that the room is heated in winter. All tools that are put away for long periods of time will be greased. A systematic record of the tools in store would be kept and any tool required could be located without loss of time.

NEW SCHOOL TO BE OPENED IN SEPTEMBER

EVENING industrial classes were organized in Sarnia in the fall of 1919. About the same time a campaign was begun with the object of passing a by-law to provide funds for the erection of a combined collegiate and technical school. This campaign was successful and the new school is now nearing completion. It will be opened in September. We believe it will be the most complete school of its size in the Province, and the total cost of building, grounds and equipment will approximate $7,000,000. The grounds comprise about 7¾ acres in the heart of the city.

During the past three winters evening classes have been conducted in the following subjects, mechanical drawing, architectural drawing, shop mathematics, auto mechanics, stationary engineering, marine engineering, masters' and mates' course, arithmetic, English, wireless, woodwork, bookkeeping, stenography, typewriting, art, French, Spanish, cooking, home nursing, fancywork, plain sewing, dressmaking, millinery, industrial physics and chemistry. The attendance has been very satisfactory in these classes considering the inferior accommodation which we have had at our disposal. With the opening of the new school the conditions will be ideal. The attendance at its highest point was nearly seven hundred.

The new school has all modern appointments. One wing is entirely devoted to technical work. There are two gymnasia, swimming pool, showers, large auditorium, fine art, science and commercial rooms. The school has a capacity of about eleven hundred students. The attendance at the institute has been growing very rapidly and is now about 540. These students will be transferred to the new school in the Fall and, in addition, the technical branch will be opened.

Getting Orders out of Unsuspected Territory

Untrained Salesmen Put This Idea Across and Brought in Good Business—Confined Their Effort to Local Field and in Two Days Proved Value of Plan

By J. H. MOORE

ENTHUSIASM and faith are the the two basic and desirable qualifications in any successful organization. Right in Toronto we have a company which can feel justly proud of asserting they have an overflow of both qualities. The firm we refer to, the Ontario Wind Engine and Pump Co., have been good enough to show us the inner workings of their executive staff, and from the managing director down, each employee is behind the company, pushing sales to the best of their ability.

A short time ago, those in charge were forced to admit that business was tapering off. "We must do something to increase sales, and keep the men working," was the predominating thought, so A. T. Thom, managing director, in conference with various members of his staff, decided to start something entirely new in the line of an intensive selling campaign. One suggestion led to another, until eventually a plan was mapped out, which for want of any better name was called the co-operative sales campaign.

The novelty of the idea lay in the fact that specialized salesmen would not be used, and that the field of activity would be the city in which they were located. In other words, an effort would be made to secure new business in Toronto, and at the same time ascertain if they themselves could buy more advantageously in their own locality. This feature made the scheme co-operative.

It was decided to use senior male members of the office staff as salesmen, or rather representatives, for the object was not simply a selling campaign. These men were paired off, and the city was divided into sections, each two men covering a previously arranged territory. It wasn't a case of picking out the chief industries of Toronto as a possible hunting ground, but rather to take a defined area and visit everything that even looked like a factory. The question was never asked, "Can we sell anything in here?" but rather the idea was, "We will go in and see if we can sell anything. If not, they may be able to sell us something." With this objective, they laid their final plans, the managing director, sales manager, collection manager, purchasing agent, etc., all joining in the effort.

In the daily newspapers, there appeared an advertisement as shown in Fig. 1. This explained briefly the object of the scheme, and appealed to the manufacturers in a direct way. The novelty of the idea took hold, and although the heralds of co-operative effort were only out two days, they found more business in that time than they had ever dreamed existed, even in their most enthusiastic moments. As Mr. Sykes, the sales director, put it, "We uncovered undreamt of possibilities, sold goods where we never expected to, and received so many enquiries that we were all swamped with work. In fact when we got back to the office Thursday morning we doubted if we would be able to give the form of service we desired, that is, the best. We felt that the scheme was a failure if we did not render first-class service, so everyone made it a point to give the company the best he had in him.

"The result being," continued Mr. Sykes, "that we have satisfied the prospects uncovered, kept our men employed, and are at present running at about 60 per cent. normal, which is not bad considering present conditions. I always feel a pang when we have to let a man go, and it is a source of keen satisfaction that the sales idea we put across, prevented such a move."

One of the reasons that this sales scheme was such an unqualified success was the careful planning that went before the actual launching of the campaign. For example, every man knew the products thoroughly which his firm had to sell, and he also knew what they required. He went into every plant with an open mind ready to discover articles his plant needed, and in many cases found them. In fact, on one call the representative found the solution of a problem that had been bothering them for some considerable time, and in a most unlooked for place. The owner of the plant visited, received an order he might never otherwise have landed, and the Ontario Wind Engine and Pump Co., were on the other hand mighty pleased to be able to thus place the order and put an end to their former troubles.

Several incidents of this nature occurred, and while they did not actually all solve problems, they did suggest better means of purchasing goods and so on. To make sure that every representative brought back accurate and standardized information the form shown at Fig. 2 was used. This was always filled in while at the plant, so that no one trusted to their memory. The fact that the men traveled in teams gave

To Toronto Manufacturers

Gentlemen:

Although our plant has operated continuously throughout the period of depression, we believe that every manufacturer should do his utmost to relieve the unemployment situation in Toronto. To do so we have developed the following co-operative plan:

On Tuesday or Wednesday of this week a representative of our firm will call on you, regardless of the nature of your product. He will not be a salesman—simply a member of our office staff. His mission will be to ascertain whether you make or could supply any article or material which we use, or if we can supply anything you require.

This is simply a straight business proposition to improve conditions in our own city. It is quite probable that there are firms in Toronto with which we are unacquainted, that could supply us with material or articles we require. It is equally probable that the opposite holds true. By co-operation, therefore, we will both be doing our part in increasing business in the city and relieving unemployment.

As our representatives have a big task before them in covering the city, we would greatly appreciate your making arrangements to have them promptly received when they call. Should our representative, by any mischance, fail to see you, a telephone message will be welcomed and personal attention given.

We manufacture and can supply promptly Grey Iron Castings, Custom Galvanizing, Machine Shop Jobbing, Wood Tanks for all purposes.

A. T. Thom
Managing Director.

them more confidence, and what one man would forget to ask, the other was sure to catch.

The co-operative effort behind the movement gave them a chance to go further than the purchasing agent. They were not solicitors for trade alone, but possible customers, and the general manager in each concern was always pleased to receive them. Problems in manufacturing were discussed frankly, and the results of the campaign can be partially understood when we mention that in one case alone, a casual visit resulted in a $7,500 order. To state in actual figures the result of this sales effort would stagger the most skeptical, but of course this is a private business matter which need not be discussed. Enough to say that all concerned are firmly convinced that it is the best thing they ever started. They are at last catching up with the enquiries which resulted from the campaign, and will soon go out in search of further business. The interest in the scheme was not confined to local manufacturers, for several firms out of town called up by phone to discover further particulars. Several merchants downtown are at present studying the scheme to see whether they can adopt it to their business, and generally speaking, the new effort has started many thinking.

The big idea behind the movement has been "Service." The staff are not content to file away the questionnaires for future reference, but are closely following up every prospect. On the road they have seven men selling their goods, this being only one less than last year, and he quit of his own accord, so that we can readily see that everyone couples his enthusiasm and faith in the products made, by actual sales.

This firm have operated their plant continuously throughout the period of depression, and as Mr. Sykes says, "We're going to keep on doing it." We feel sure that if consistent effort, plus enthusiasm count for anything, they will have no trouble in this respect. The idea contained in this sales story can be carried into other fields, and anyone desiring further particulars will receive it freely from the company already mentioned, as they are fully convinced that the more manufacturers cooperate with each other, the sooner business will reach normal.

THE WORKING OF METALS

"The rolling of metals appears to be complicated by so many variables," said Dr. F. Johnson at a meeting of the Birmingham Metallurgical Society, "that it defies at present a purely theoretical analysis.

"For a given condition of the metal the velocity of flow was proportional to a difference between the actual shearing stress. Therefore a slow rate of rolling would produce lower stresses in the metal than would a fast rate. In cold rolling 90 per cent. of the resistance to rolling was accounted for by roll-neck friction. In the rolling of metal plates and bars there always occurred an amount of lateral spread. A knowledge of the amount of spread for a given material and a given reduction was necessary, because too much spread would over-fill a pass and produce fins, whilst insufficient spreading would result in under-filling of the pass and an imperfect shape.

"One of the greatest factors influencing spreading was the extent and shape of the projected contact area. In rolling rods the splaying of grooves was adopted in order to produce fins of such a shape that by turning the rod through an angle of 90 deg. at the next pass the fins might be pressed back into the rod. No roll grooves were perfectly circular. Even the finishing pass allowed for a slight amount of inevitable side-spread by having the rolls left slightly apart."

LARGEST CIRCULAR SAWS IN THE WORLD

The accompanying illustration shows two of the largest saws ever made for lumbering operations. These were manufactured by Disston & Sons for work on the Pacific Coast. These saws are 9 feet in diameter, each having 190 detachable teeth inserted in the rim, a feature that facilitates repairs. Great care was necessary in the production of the ingots and plates, as the latter had to be exactly flat and true, The rough ingots contained 1,140 lbs. of the steel and the finished disc weighed 795 lbs. The teeth attain a speed of 130 miles an hour

Micrometers Make Standardization Possible

Obtaining Measurement More Accurately—Care Should be Exercised in Making Adjustments—Fine Tools Affected by Change of Temperature—Keep Tools in Cases When Not in Use

NO OTHER instrument has done more to assist the mechanic to make precision measuring a reality than the micrometer. The young machinist or tool maker, just embarking on a shop career, always considers it a red letter day when he becomes the proud possessor of his first "mike," usually the 0 to 1 inch size in an attractive case, with a 1 inch standard disc. The fact of their possession, always lends an air of superiority to the possessor as he strives to create opportunities that necessitate their use.

Going back nearly four generations we find the prototype of to-day's micrometer caliper in a French tool called "Systeme Palmer." It was during a visit to the Paris exposition in 1867 that Messrs. J. A. Brown and Lucian Sharpe were impressed with its possibilities. Earlier in the same year a brass

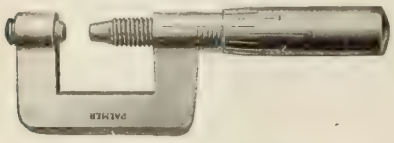

Fig. 1.—"Systeme Palmer."

manufacturing concern in America, encountered trouble when one of its shipments were returned because it was "out of gauge." Of the three U. S. standard gauges then in use, no two agreed. The unfortunate manufacturer conceiving the idea of a measuring tool, sent a sketch to Messrs. Brown and Sharpe for experimental work. The tool was not of practical commercial value as it was difficult to read. The need of a tool, capable of measuring sheet metal accurately and quickly was apparent, and in the same year was produced the "pocket sheet metal gauge" adopting the Palmer system of divisions, and also adding means of compensation for wear of both the screw and measuring surfaces.

Principle of the Micrometer Caliper

One may define the only mechanical principle of a micrometer as a screw free to move in a fixed nut. The backward movement of this screw affords an opening for the work to be measured. The size is indicated by the graduation. Fig. 3 shows a standard design of micrometer caliper. As the frame is stationary, the spindle C, which is attached to the sleeve at E, approaches or recedes from the anvil B, when the sleeve is revolved. The graduations on the hub A, are in a line parallel to the axis of the screw and conform to the pitch of the screw. The bevelled edge of the sleeve D carries graduations which enable reading in one-thousandths of an inch to be taken.

The customary pitch of the screw is 1-40 of an inch. (40 threads to the inch). Thus the distance traversed by the screw or spindle during one complete revolution is 1-40 of an inch or .025 inches. As the graduations on the hub conform to the pitch of the screw (40 to the inch) each division equals .025 inches, and every four divisions represent 0in., .100in. .200 in. etc. (10ths of an inch) each tenth of an inch is numbered 0, 1, 2, etc. The bevelled edge of the sleeve is graduated into twenty-five parts and figured every fifth division 0, 5, 10, 15, 20. When twenty-five of these graduations have passed the horizontal line on the hub, the spindle having made one revolution, has moved .025 inches. Thus when the spindle moves only far enough to cause one graduation to pass the horizontal line on the hub it will have moved 1-25 of .025 inches or .001 inches. The distance between the graduations on the sleeve is great enough to permit half and quarter thousandths to be readily estimated.

To read—first note the last figures visible on the scale of the hub, representing the tenths of an inch. Multiply the number of divisions visible beyond this figure by twenty-five and add the number of the division on the scale on the sleeve that coincides with the graduations on the hub. Then the tenths shown, added to this sum expressed in thousandths, is the reading. Example:—In Fig. 4, .200 inches (2-10 inches) are shown by the figures in the scale on the hub, and one graduation is also visible, while on the bevel on the sleeve the graduations show sixteen divisions from the zero to the line coincident with the horizontal line on the hut Then the reading is .200 in. plus .025 in. plus .016 in. which is .241 in.

Measuring to Ten-Thousandths

To obtain readings in ten-thousandths of an inch a vernier is employed on the hub of the micrometer caliper, as shown in Figs. 5 and 6. The vernier used consists of ten divisions which equal, in overall space, nine divisions on the sleeve. Thus one division on the vernier equals 1-10 of 9-1000 in. equals 9-10,000 in. Since each graduation on the sleeve is 1-100 in. or 10110,000 in. the difference in space between a division on the sleeve and a division on the hub equals 10-10,000 in. minus 9-10,000 in. equals 1-10,000 in. Since the two zero lines on the vernier coincide with lines on the sleeve when the reading is exact with respect to the number of thousandths, the difference between the lines on the sleeve and the lines on the vernier at numbers 1, 2, 3, etc. equals .0001 in., .0002 in., .0003 in., etc. Thus when the first second or third, etc. lines coincide, the sleeve has moved past the exact zero setting 1, 2,

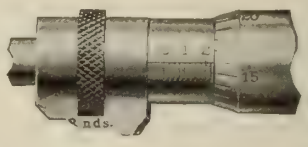

Fig. 4.—Standard graduations for measuring thousandths of an inch.

or 3, etc. ten-thousandths parts of an inch to bring these lines together.

To read—first obtain the reading for the thousandths in the manner described in the preceding section and then add the ten-thousandths, the number of which is indicated by the line on the vernier which coincides with a line on the sleeve. Example:—As shown in Fig. 6 (right) there are no ten thousandths to be added for two zeros on the vernier coincide with lines on the sleeve; the reading is .4690 in. In the lower cut the 7th graduation on the vernier coincides with a line on the sleeve, indicating that 7 ten thousandths should be added to the thousandths reading; the reading is .4690 in. plus .0007 in. which is .4697 in.

The Ratchet Stop

The ratchet stop, as shown in Fig. 8, is convenient for a series of measurements. In using it, it is necessary to move the stop only far enough to furnish two clicks of the racket. This furnishes enough pressure. In other words a short extension of the barrel is furnished. This extension is so arrang-

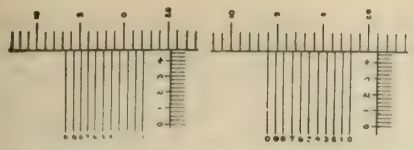

Fig. 6.—Diagram of vernier scale.

ed that it can be made to revolve the barrel, positively in a direction tended to open or increase the distance between the anvil and spindle, and in the opposite direction a ratchet slips when a predetermined pressure on any object to be gauged, is exerted. Without the ratchet stop a micrometer would be closed down on an object with a different pressure every time, which difference in pressure might result in slightly varying results being obtained.

Clamp Ring

The clamp ring as shown in Fig. 9 is a device for clamping the spindle when the desired setting has been obtained. It is useful in calipering similar pieces which are finished to the same size. The knurled ring when turned, causes an inner band through which the micrometer spindle passes, to contract, making its diameter small enough to grip the spindle from all sides and not disturb the setting for the forces all act toward a common centre. An ordinary pressure is sufficient to hold the spindle firmly. In connection with the clamp ring it must be remembered that its construction is such that it will be ruined should the clamp be tightened when the spindle is removed.

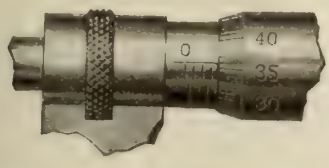

Fig. 7.—Metric graduations.

Adjustments

With ordinary treatment a micrometer caliper can be used for a long time without adjustment. However, in case it should be necessary, means are incorporated in its design for taking up the wear of the screw, and also for correcting the reading when the micrometer is set at zero. Fig. 10 shows the method of taking up wear or play in the screw. The sleeve, with the spindle, is removed and placed where it will be free from dust, preferably on a clean piece of paper. The slots in the tapered nut can be seen, and, using the special wrench furnished with the caliper, turn the nut on the thread which is also tapered. Since that part of the hub containing the threads is split, a very slight turn reduces the diameter of the thread enough to make the screw snug. The cut shows the sleeve removed and the wrench in hand for making the adjustment. The adjustment made, the sleeve should be rolled between the palms of the hands to insure the threads working smoothly. Fig. 11 shows the means of adjusting the zero on the caliper to the correct reading, should the anvil or spindle become worn.

In "trying" for adjustment it is necessary to have the measuring surfaces of the anvil and spindle clean. A good method is to bring these two surfaces together on a clean sheet of paper and then draw out the paper, which the pressure should just permit. Screw A should be turned to the left just enough to assure that the back lash in the screw will be taken up when turned to the right, (advance) for only a slight turn is usually required in bringing up the anvil. The micrometer should then be tried for its zero reading, the measuring surfaces having been first cleaned. If the anvil has not been brought up enough give another very slight turn and repeat by successive movements if necessary, until the zero reading is exactly correct. However, care should be taken not to bring the anvil up too far, for if this is done it is necessary to repeat the entire operation to eliminate back lash. Screw B should not be touched unless it is found impossible to move screw A, and then it should be turned very carefully, for it is apt to turn the anvil when moved. It is merely a binding screw.

Figs. 10 and 11 show the instrument held by a vise with leather faced jaws, and although not necessary, it gives a firm support and the effect from the heat of the hand is greatly reduced. Aside from the vise, only an ordinary screw driver is required. Although adjustments can be made as illustrated above, manufacturers maintain a staff of workmen skilled in this work which they perform under ideal conditions and if at all possible instruments should be returned to the factory for adjustment

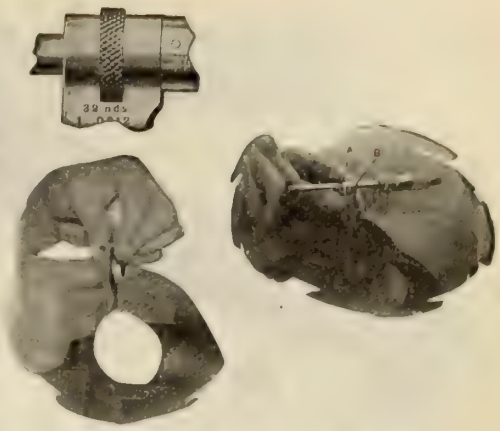

Fig. 9.—(Top left) clamp ring. Fig. 10—Adjusting for wear. Fig. 11—Correcting the zero reading.

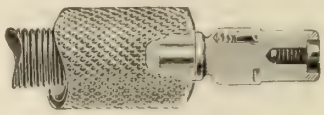

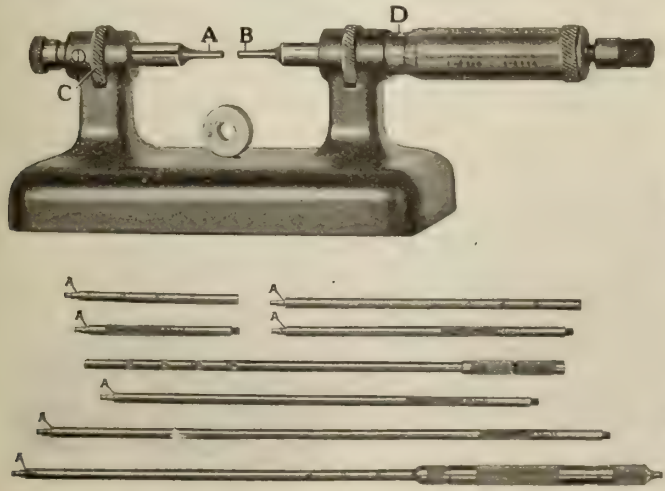

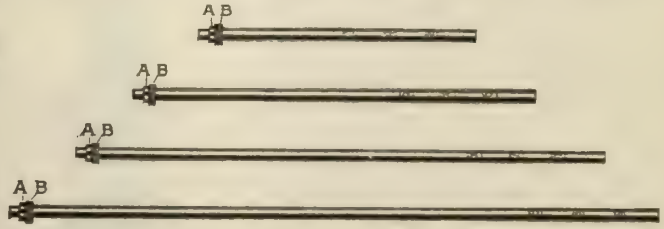

Fig. 8.—The ratchet stop.

Lubrication

In oiling, only the very best quality of a very light oil should be used, and this in a small quantity. Light sewing machine oil, or gun oil is best. It is very unwise to use a heavy oil. The spindle should be removed and the threads cleaned with pure naphtha. When the instrument is dry and free from any traces of naphtha, the oil should be placed on the threads and the spindle then turned back, the oil working into the threads as it returns. A clean tooth pick is very convenient for placing oil on the threads. Before oiling clean the spout of the oil can and shake out a few drops of oil through

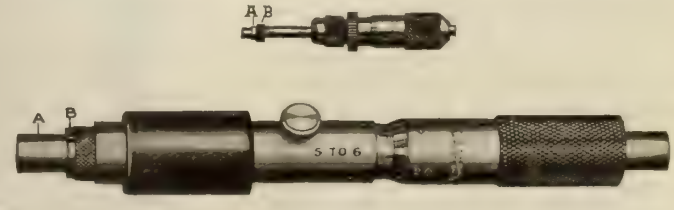

Fig. 12.—Bench micrometer. Fig. 14—Inside micrometer caliper. Fig. 13.—Inside micrometer caliper. Fig. 15.—Tubular inside micrometer caliper.

it to remove any dust and dirt, as the oil must be clean.

Care and Use

The satisfaction derived from a micrometer caliper is dependent upon the care and use given it, because it requires but very little maltreatment to throw a high grade precision tool out of adjustment. The micrometer should be taken apart only when absolutely necessary, for any dirt or grit which might enter is very detrimental to its successful operation, and very injurious to the threads. In the grinding it is a very easy matter for emery to find its way into the screw which rapidly reduces its accuracy. There are in addition many other adverse conditions which the instrument must contend with and the user must be careful to protect it as much as possible in all instances.

In measuring, bring the measuring surfaces up to the work to be calipered slowly. Only a light pressure is required for accurate results. If brought up too forcibly an incorrect reading usually results. This is specially true of calipers graduated to ten-thousandths of an inch, and the use of this type of tool should be restricted to fine measurements as wear which would be of comparatively slight consequence in a caliper that reads only to thousandths, is not only perceptible but important in a tool of this class. It is well to remember that the heat of the hand, the cutter, or the work, will make a momentary difference in the reading. To avoid this, the tool should be placed in a spot unaffected by heat until it is required for actual service. In putting the tool away for any length of time, it should be thoroughly cleaned with a first quality of naphtha, and then covered with a coating of oil to prevent rust. If naphtha is used, instrument should be free from all traces of it, before the oil is applied. It is also a very good plan to wrap in oil paper also, as this excludes dust, dampness, etc.

Bench Micrometer Caliper

Fig. 12 illustrates the bench micrometer caliper reading measurements from 0 to slightly over 1 inch. The micrometer principle employed is just the same as in the portable instrument. To obtain readings much the same rules are followed. In calipering distances between 0 and ½ inch, set the caliper at zero and push the anvil A until the measuring surfaces of the anvil A and spindle B just touch. Then tighten the clamp ring C. To obtain readings from ½ to 1 inch set the caliper at zero and fasten by tightening its clamp ring. Push the anvil A back until the standard half inch gauge furnished with the caliper fits in the opening between the measuring points. Then tighten the clamp ring C and make the anvil fast. In measuring with this instrument it is just as important, as with the portable type of micrometer, to have the anvil and spindle clean, and adjustments should be carefully made. The hub D is graduated from 0 to 1 inch and this permits a range greater than 1 inch, using the standard gauge furnished. The adjustments for wear on the screw or thread are made similarly to those on the micrometer caliper.

Inside Micrometers

Fig. 13 shows a standard inside micrometer. As will be noted, rods of various lengths are provided which enables the micrometer to be used on a wide range of dimensions. The rods are easily detachable and any one can be quickly placed in the instrument. The whole inches are obtained from the known

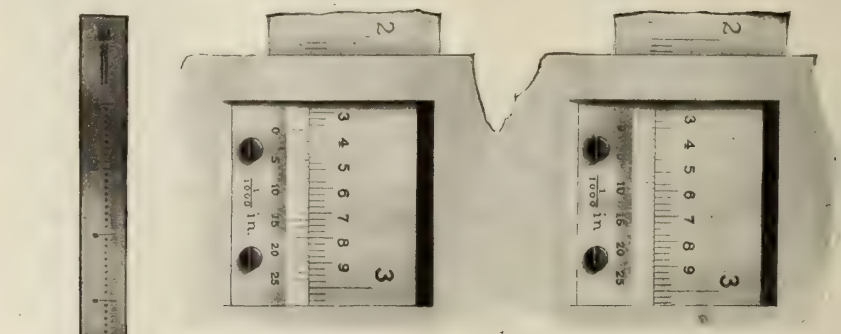

Fig. 19.—Vernier caliper. Fig. 20.—Enlarged view of graduations.

length of the rod inserted, or, expressed in another way, the distance between the measuring points when the instrument is set to zero, is known for each rod inserted and this constitutes the reading in whole inches. The reading in thousandths is obtained by the same method as employed when reading an outside micrometer caliper. The two readings, namely whole inches and thousandths, are added to obtain the complete dimension. Thread and wear adjustments are made as before described.

Adjustment of the zero on the micrometer to the correct reading is made in a slightly different manner than that described in a previous paragraph, as the method applicable to outside micrometers. This is accomplished by adjusting the nut A on each of the rods. With the micrometer set at zero, insert the rod on which it is desired to make an adjustment, and loosen slightly its lock nut B. The measuring surfaces should be clean in making adjustments. Then adjust the nut A until the correct length is obtained and tighten the lock nut B. As in the case of all adjustments to precision instruments great care should be exercised. Also care should be taken in changing or inserting rods, not to force the chuck fingers which hold the rods in the micrometer. If these become worn the instrument should be returned to the factory for repair, as its accuracy cannot then be relied upon.
